

Beyond Higgs: Physics of the Massless Phase

Frank Dodd (Tony) Smith, Jr. - 2013 vixra 1303.0166

At Temperature / Energy above $3 \times 10^{15} \text{ K} = 300 \text{ GeV}$:
the Higgs mechanism is not in effect so there is full ElectroWeak Symmetry
and no particles have any mass from the Higgs.

Questions arise:

1 - Can we build a collider that will explore the Massless Phase ?

Page 2

2 - How did our Universe evolve in that early Massless Phase of its first 10^{-11} seconds or so ?

Page 3

3 - What do physical phenomena look like in the Massless Phase ?

A - ElectroWeak Particles behave more like Waves than Particles.

Page 5

B - Conformal Gravity Dark Energy whose GraviPhotons might be accessible to experiments using BSCCO Josephson Junctions.

I. E. Segal proposed a Minkowski-Conformal 2-phase Universe and

Beck and Mackey proposed 2 Photon-GraviPhoton phases:

Minkowski/Photon phase locally Minkowski with ordinary Photons and
weak Gravity.

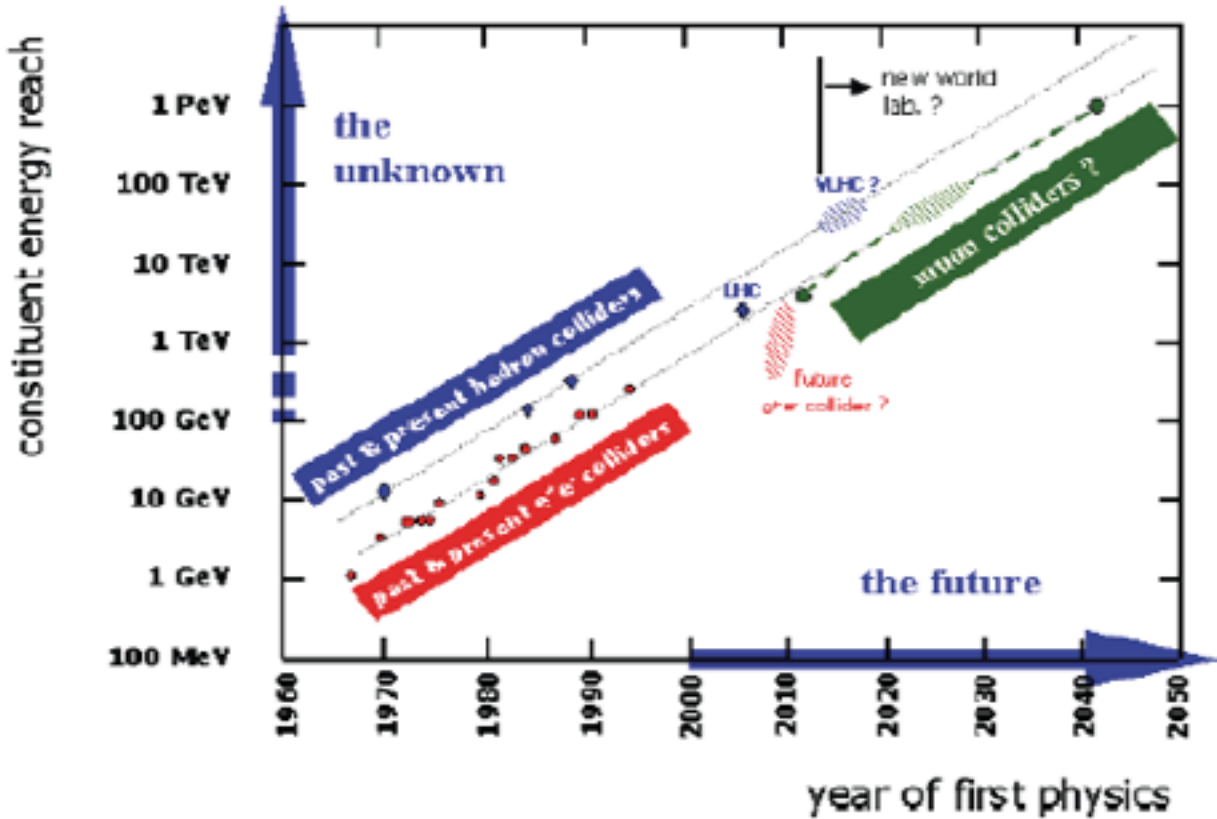

Conformal/GraviPhoton phase with GraviPhotons and

Conformal massless symmetry and consequently strong Gravity.

Page 6

1 - Can we build a collider that will explore the Massless Phase ?

Yes: In hep-ex00050008 Bruce King has a chart and he gives a cost estimate of

about \$12 billion for a 1000 TeV (1 PeV) Linear Muon Collider with tunnel length about 1000 km. Marc Sher has noted that by now (late 2012 / early 2013) the cost estimate of \$12 billion should be doubled or more. My view is that a cost of \$100 billion is easily affordable by the USA as it is far less than the Trillions given annually since 2008 by the USA Fed/Treasury to Big Banks as Quantitative Easing to support their Derivatives Casino.

Science will advance AND non-Bankster people will get paying jobs.

2 - How did our Universe evolve in that early Massless Phase of its first $10^{(-11)}$ seconds or so ?

In the context of E8 Physics as described at vixra 1108.0027 our Universe began as a Quantum Fluctuation from a Parent Universe whereby

our Universe initially had Planck Scale Temperature / Energy
 $10^{32} \text{ K} = 1.22 \times 10^{19} \text{ GeV}$.

Its physics was then described by a Lagrangian with:

Gauge Boson term of 28-dimensional adjoint Spin(8) that eventually produces 16-dim U(2,2) Conformal Gravity/Higgs and the 12-dim SU(3)xSU(2)xU(1) Standard Model;

Fermion term of 8-dimensional half-spinor Spin(8) corresponding to first-generation fermion particles and antiparticles (electron, RGB Up quarks; neutrino, RGB down quarks);

Base Manifold of 8-dimensional Octonionic Spacetime.

With respect to 8-dimensional Spacetime

the dimensionality of the Gauge Boson term is $28 \times 1 = 28$
and

the dimensionality of the Fermion term is $8 \times 7/2 = 28$

(see Weinberg's 1986 Dirac Memorial Lecture at page 88
and note that $7/2 + 7/2 + 1 = 8$)

so

the E8 Physics Lagrangian is clearly Ultraviolet Finite at the Planck Scale due to Triality-based cancellations, an effective Subtle Supersymmetry. Since the lower energy forms of E8 Physics are derived from the Planck Scale Lagrangian, they also benefit from the cancellations.

As Our Universe began to cool down below the Planck Scale

Inflationary Expansion started due to Octonionic Quantum Non-Unitarity

(see Adler's book "Quaternionic Quantum Mechanics ..." at pages 50-52 and 561).

Paola Zizzi describes the Octonionic Inflationary Era in terms of Clifford Algebras in gr-qc/0007006 and related papers. In short, the 64 doublings of Zizzi Inflation produce about 10^{77} fermion particles.

At the End of Inflation Our Universe had Temperature / Energy
 $10^{27} \text{ K} = 10^{14} \text{ GeV}$

A consequence of the end of Octonionic Inflation was the freezing out of a preferred Quaternionic Subspace so that 8-dim Octonionic Spacetime was converted into (4+4)-dim Kaluza-Klein spacetime $M_4 \times CP^2$ where M_4 is Minkowski Physical 4-dim spacetime and $CP^2 = SU(3) / SU(2) \times U(1)$ is a Batakis 4-dim Internal Symmetry Space. The geometry of that splitting of spacetime produces a Higgs mechanism. (see Meinhard Mayer and A. Trautman in "A Brief Introduction to the Geometry of Gauge Fields" and "The Geometry of Symmetry Breaking in Gauge Theories", Acta Physica Austriaca, Suppl. XXIII (1981))

Since each of the 10^{77} fermions had energy of 10^{14} GeV collisions among them would for each of the 10^{77} fermions produce jets containing about 10^{12} particles of energy 100 GeV or so so that the total number of such particles is about 10^{89} .

According to Weinberg's book "Cosmology":

"... above 10^{13} K , nucleons would not yet have formed from their three constituent quarks, and there would have been roughly as many quark-antiquark pairs in thermal equilibrium as photons ... before annihilation there must have been a slight excess ... of quarks over antiquarks, so that some quarks would survive to form nucleons when all the antiquarks had annihilated with quarks. There was also a slight excess of electrons over positrons, to maintain charge neutrality of the universe ...".

Therefore, in the interval

between **the End of Inflation** and **ElectroWeak Symmetry Breaking** most of the quarks in 10^{89} fermions formed quark-antiquark pairs that produced as a condensate the Higgs that is needed for Mayer-Higgs. The quark-antiquark condensate Higgs then

Breaks ElectroWeak Symmetry at Temperature / Energy
 $3 \times 10^{15} \text{ K} = 300 \text{ GeV}$

and gives mass to particles and at age $10^{-(11)}$ seconds
ends the Massless Phase of the history of Our Universe.

3 - What do physical phenomena look like in the Massless Phase ?

Two points of view are important:

ElectroWeak Particles and Dark Energy Conformal Gravity

ElectroWeak Particles:

The Weak Force Strength is $0.2535 \times (1 / MW^2) = 1.05 \times 10^{-5}$ where MW is a Weak Boson Mass factor that goes away in the Massless Realm where the Weak Force becomes a strong 0.25345.

As to Kobayashi-Maskawa Weak Force mixing in the Massless Realm, Kea (Marni Sheppard) proposed that in the Massless Realm the mixing matrix might be democratic which to me means that in the Massless Realm you might say that there is just a democratic mixing matrix of the form $1/3 \times$

$$\begin{matrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{matrix}$$

with no complex terms and no CP violation in the Massless Realm.

With no mass terms, the structure of particle interactions would be based on the Wave Picture instead of the Particle Picture. Instead of a particle with mass moving slower than light the picture is a massless particle moving at light speed with its energy defined by its frequency.

In that picture, for example, a Muon is distinguishable from an electron by higher frequency due to the 2-fold 4+4 path of second generation fermions instead of simple 4 path of first generation fermions.

Quark wave paths have $S7 \times RP1$ structure whose greater complexity produces higher frequency than Lepton wave paths.

Bound structures (Hadrons, Mesons, Nuclei, Atoms, etc) are based on standing wave frequencies instead of masses of particles, nuclei, etc.

Conformal Gravity Dark Energy:

I. E. Segal proposed a Minkowski-Conformal 2-phase Universe and

Beck and Mackey proposed 2 Photon-GraviPhoton phases:

Minkowski/Photon phase locally Minkowski with ordinary Photons and Gravity weakened by $1 / (M_{\text{Planck}})^2 = 5 \times 10^{(-39)}$.

so that we see Dark Energy as only 3.9 GeV/m^3

Conformal/GraviPhoton phase with GraviPhotons and Conformal symmetry (like the massless phase of energies above Higgs EW symmetry breaking) With massless Planck the $1 / M_{\text{Planck}}^2$ Gravity weakening goes away and the Gravity Force Strength becomes the strongest possible = 1 so Conformal Gravity Dark Energy should be enhanced by M_{Planck}^2 from the Minkowski/Photon phase value of 3.9 GeV/m^3 .

The Energy Gap of our Universe as superconductor condensate spacetime is from

from $3 \times 10^{(-18)} \text{ Hz}$ (radius of universe) to $3 \times 10^{43} \text{ Hz}$ (Planck length) and

its RMS amplitude is $10^{13} \text{ Hz} = 10 \text{ THz} = \text{energy of neutrino masses} =$
 $= \text{critical temperature } T_c \text{ of BSCCO superconducting crystals.}$

Neutrino masses are involved because their mass is zero at tree level and their masses that we observe come from virtual graviphotons becoming virtual neutrino-antineutrino pairs.

BSCCO superconducting crystals are by their structure natural Josephson Junctions. Dark Energy accumulates (through graviphotons) in the superconducting layers of BSCCO.

Josephson Junction control voltage acts as a valve for access to the BSCCO Dark Energy, an idea due to Jack Sarfatti.

In E8 Physics Dark Energy comes from the Conformal/GraviPhoton phase. The geometry of the Conformal Sector is closely related to the Penrose Paradise of Twistors. Yu. Manin in his 1981 book "Mathematics and Physics" said: "... In a world of light there are neither points nor moments of time; beings woven from light would live "nowhere" and "nowhen" ... the whole life history of a free photon [is] the smallest "event" that can happen to light. ...".

Here is how the Conformal/GraviPhoton phase of Gravity works:
The Lorentz Group is represented by 6 generators

$$\begin{array}{cccc}
 0 & J1 & J2 & M1 \\
 -J1 & 0 & J3 & M2 \\
 -J2 & -J3 & 0 & M3 \\
 -M1 & -M2 & -M3 & 0
 \end{array}$$

There are two ways to extend the Lorentz Group:

(see arXiv gr-qc/9809061 by Aldrovandi and Peireira):

to the Poincare Group of Minkowski Space with No Cosmological Constant of the Minkowski/Photon phase where ordinary Photons usually live by adding 4 generators

$$\begin{array}{cccccc}
 0 & J1 & J2 & M1 & & A1 \\
 -J1 & 0 & J3 & M2 & & A2 \\
 -J2 & -J3 & 0 & M3 & & A3 \\
 -M1 & -M2 & -M3 & 0 & & A4 \\
 \\
 -A1 & -A2 & -A3 & -A4 & & 0
 \end{array}$$

{A1,A2,A3} represent Momentum
and {A4} represents Energy/Mass of Poincare Gravity
and its Dark Matter Primordial Black Holes

and

to the semidirect product of Lorentz and 4 Special Conformal generators to get a Non-Zero Cosmological Constant for Universe Expansion of the Conformal/GraviPhoton phase where GraviPhotons usually live

0	J1	J2	M1	G1
-J1	0	J3	M2	G2
-J2	-J3	0	M3	G3
-M1	-M2	-M3	0	G4
-G1	-G2	-G3	-G4	0

so that {G1,G2,G3} represent 3 Higgs components giving mass to 3 Weak Bosons and {G4} represents massive Higgs Scalar as Fermion Condensate. As Special Conformal and Scale Conformal degrees of freedom they also represent the Momentum of Expansion of the Universe and Dark Energy.

One more generator {G5} represents Higgs mass of Ordinary Matter. All 15 generators combine to make the full Conformal Lie Algebra $SU(2,2) = Spin(2,4)$ of the universal Conformal Space with a Non-Zero Cosmological Constant for Universe Expansion

0	J1	J2	M1	G1	A1
-J1	0	J3	M2	G2	A2
-J2	-J3	0	M3	G3	A3
-M1	-M2	-M3	0	G4	A4
-G1	-G2	-G3	-G4	0	G5
-A1	-A2	-A3	-A4	-G5	0

10 generators in the 5x5 upper diagonal correspond to Dark Energy (DE) the 4 upper generators of the 6th column correspond to Dark Matter (DM) the 5th generator of the 6th column corresponds to Ordinary Matter (OM)

The basic 10 : 4 : 1 = 67 : 27 : 06 ratio of DE : DM : OM has evolved over the history of Our Universe to its present value of
DE : DM : OM = 75 : 20 : 05 (rough evolution calculation)
DE : DM : OM = 73 : 23 : 04 (measured by WMAP)
DE : DM : OM = 69 : 26 : 05 (measured by Planck)

Rabindra Mohapatra in section 14.6 of his book "Unification and Supersymmetry" said:
 "... we start with a Lagrangian invariant under full local conformal symmetry and fix its conformal and scale gauge to obtain the usual action for gravity ... the conformal d'Alembertian contains ... curvature ... R , which for constant ...

scalar field ... Φ , leads to gravity. We may call Φ the auxiliary field ...".
 I view Φ as corresponding to the Higgs 3 Special Conformal generators $\{G1, G2, G3\}$ that are frozen fixed during expansion in some regions of our **Universe** to become **Gravitationally Bound Domains** (such as **Galaxies**) like icebergs in an ocean of water.

Since the **Gravitationally Bound Domains** (such as our Inner Solar System) have no Expansion Momentum we only see there the Poincare Part of Conformal Gravity plus the Higgs effects of $\{G4\}$ and $\{G5\}$ and the ElectroWeak Broken Symmetry caused by freezing-out fixing $\{G1, G2, G3\}$:

0	J1	J2	M1	-	A1
-J1	0	J3	M2	-	A2
-J2	-J3	0	M3	-	A3
-M1	-M2	-M3	0	G4	A4
-	-	-	-G4	0	G5
-A1	-A2	-A3	-A4	-G5	0

Each long BSCCO single crystal looks geometrically like a line so configure the JJ Array using BSCCO crystals as edges.

The simplest polytope, the Tetrahedron, is made of 6 edges: Feigelman, Ioffe, Geshkenbein, Dayal, and Blatter in cond-mat/0407663 said: “... Superconducting tetrahedral quantum bits ...”

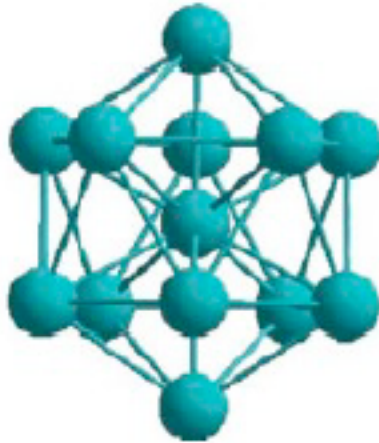

FIG. 1: (a) Tetrahedral superconducting qubit involving four islands and six junctions (with Josephson coupling E_J and charging energy E_C); all islands and junctions are assumed to be equal and arranged in a symmetric way. The islands are attributed phases ϕ_i , $i = 0, \dots, 3$. The qubit is manipulated via bias voltages v_i and bias currents i_i . In order to measure the qubit's state it is convenient to invert the tetrahedron as shown in (b) — we refer to this version as the ‘connected’ tetrahedron with the inner dark-grey island in (a) transformed into the outer ring in (b). The measurement involves additional measurement junctions with couplings $E_m \gg E_J$ on the outer ring which are driven by external currents I_m (schematic, see Fig. 6 for details); the large coupling E_m effectively binds the ring segments into one island.

... tetrahedral qubit design ... emulates a spin-1/2 system in a vanishing magnetic field, the ideal starting point for the construction of a qubit. Manipulation of the tetrahedral qubit through external bias signals translates into application of magnetic fields on the spin; the application of the bias to different elements of the tetrahedral qubit corresponds to rotated operations in spin space. ...”

42 edges make an Icosahedron plus its center

(image from Physical Review B 72 (2005) 115421 by Rogan et al)

with 30 exterior edges and 12 edges from center to vertices.
It has 20 cells which are approximate Tetrahedra in flat 3-space
but become exact regular Tetrahedra in curved 3-space.

Could an approximate-20Tetrahedra-Icosahedron configuration
of 42 BSCCO JJ tap into Dark Energy so that the Dark Energy
might regularize the configuration to exact Tetrahedra and so
curve/warp spacetime from flat 3-space to curved 3-space ?

720 edges make a 4-dimensional 600-cell

(image from Wikipedia)

At each vertex 20 Tetrahedral faces meet forming an Icosahedron which is exact because the 600-cell lives on a curved 3-sphere in 4-space. It has 600 Tetrahedral 3-dim faces and 120 vertices

Could a 600 approximate-Tetrahedra configuration of 720 BSCCO JJ approximating projection of a 600-cell into 3-space tap into Dark Energy so that the Dark Energy might regularize the configuration to exact Tetrahedra and an exact 600-cell and so curve/warp spacetime from flat 3-space to curved 3-space ?

The basic idea of Dark Energy from BSCCO Josephson Junctions is based on the 600-cell as follows: Consider 3-dim models of 600-cell such as metal sculpture from Bathsheba Grossman who says:

"... for it I used an orthogonal projection rather than the Schlegel diagrams of the other polytopes I build.
... In this projection all cells are identical, as there is no perspective distortion. ...".

For the Dark Energy experiment each of the 720 lines would be made of a single BSCCO crystal

whose layers act naturally to make the BSCCO crystal an intrinsic Josephson Junction. (see Wikipedia and arXiv 0911.5371)

Each of the 600 tetrahedral cells of the 600-cell has 6 BSCCO crystal JJ edges.
Since the 600-cell is in flat 3D space the tetrahedra are distorted.

According to the ideas of Beck and Mackey (astro--ph/0703364) and of Clovis Jacinto de Matos (arXiv 0707.1797) the superconducting Josephson Junction layers of the 720 BSCCO crystals will bond with Dark Energy GraviPhotons that are pushing our Universe to expand.

My idea is that the Dark Energy GraviPhotons will not like being configured as edges of tetrahedra that are distorted in our flat 3D space and they will use their Dark Energy to make all 600 tetrahedra to be exact and regular by curving our flat space (and space-time).

My view is that the Dark Energy GraviPhotons will have enough strength to do that because their strength will NOT be weakened by the $(1 / M_{\text{Planck}})^2$ factor that makes ordinary gravity so weak.

It seems to me to be a clearly designed experiment that will either
1- not work and show my ideas to be wrong or
2 - work and open the door for humans to work with Dark Energy.

Consider BSCCO JJ 600-cells

in this configuration:

First put 12 of the BSCCO JJ 600-cells at the vertices of a cuboctahedron shown here as a 3D stereo pair:

Cuboctahedra do not tile 3D flat space without interstitial octahedra

but BSCCO JJ 600-cell cuboctahedra can be put together square-face-to-square-face in flat 3D configurations including flat sheets. As Buckminster Fuller described, the 8 triangle faces of a cuboctahedron

give it an inherently 4D structure consistent with the green cuboctahedron

central figure of a 24-cell (3D stereo 4thD blue-green-red color) that tiles flat Euclidean 4D space.

So, cuboctahedral BSCCO JJ 600-cell structure likes flat 3D and 4D space but if BSCCO JJ Dark Energy act to transform flat space into curved space like a 720-edge 600-cell with 600 regular tetrahedra then Dark Energy should transform cuboctahedral BSCCO JJ 600-cell structure into a 720-edge BSCCO JJ 600-cell structure that likes curved space.

There is a direct Jitterbug transformation of the 12-vertex cuboctahedron to the 12-vertex icosahedron

whereby the 12 cuboctahedron vertices as midpoints of octahedral edges are mapped to 12 icosahedron vertices as Golden Ratio points of octahedral edges. There are two ways to map a midpoint to a Golden Ratio point. For the Dark Energy experiment the same choice of mapping should be made consistently throughout the BSCCO JJ 600-cell structure.

The result of the Jitterbug mapping is that each cuboctahedron in the BSCCO JJ 600-cell structure with its 12 little BSCCO JJ 600-cells at its 12 vertices is mapped to an icosahedron with 12 little BSCCO JJ 600-cells at its 20 vertices:

and the overall cuboctahedral BSCCO JJ 600-cell structure is transformed into an overall icosahedral BSCCO JJ 600-cell structure

does not fit in flat 3D space in a naturally characteristic way (This is why icosahedral QuasiCrystal structures do not extend as simply throughout flat 3D space as do cuboctahedral structures).

However,
the BSCCO JJ 600-cell structure Jitterbug icosahedra
do live happily in 3-sphere curved space within the icosahedral 120-cell
(see Wikipedia)

which has the same 720-edge arrangement as the 600-cell.

The icosahedral 120-cell is constructed by 5 icosahedra around each edge.
It has:

cells - 120 {3,5}
faces - 1200 {3}
edges - 720
vertices - 120
vertex figure - {5,5/2}
symmetry group $H_4, [3,3,5]$
dual - small stellated 120-cell

6720 edges make an 8-dimensional Witting 4₂₁ Polytope

 <p style="text-align: center;">4₂₁</p>	 <p style="text-align: center;">600-cell</p>

Wikipedia said "... The 4₂₁ is related to the 600-cell by a geometric folding of the Coxeter-Dynkin diagrams. This can be seen in the E₈/H₄ Coxeter plane projections. The 240 vertices of the 4₂₁ polytope are projected into 4-space as two copies of the 120 vertices of the 600-cell, one copy smaller

than the other [by the Golden Ratio] with the same orientation. Seen as a 2D orthographic projection in the E8/H4 Coxeter plane, the 120 vertices of the [larger] 600-cell are projected in the same four rings as seen in the 4_21. The other 4 rings of the 4_21 graph ... match ... the four rings of the ... smaller ... 600-cell.

...

The 4_21 ... is the vertex figure for a uniform tessellation of 8-dimensional space, represented by symbol 5_21

...

The vertex arrangement of 521 is called the E8 lattice ... the E8 lattice can ... be constructed as a union of the vertices of two 8-demicube honeycombs (called a D82 or D8+ lattice)

...

Each point of the E8 lattice is surrounded by 2160 8-orthoplexes and 17280 8-simplices. The 2160 deep holes near the origin are exactly the halves of the norm 4 lattice points. The 17520 norm 8 lattice points fall into two classes (two orbits under the action of the E8 automorphism group): 240 are twice the norm 2 lattice points while 17280 are 3 times the shallow holes surrounding the origin

...".

An E8 lattice represents an Integral Domain of the Octonions. There are 480 Octonion Multiplications and there are 7 E8 lattice Octonion Integral Domains.

The structures of E8 Physics (including Conformal Gravity Dark Energy) are naturally compatible with a 6720-edge configuration.

Klee Irwin is also working on projections of E8 lattices into 3-space QuasiCrystal structures that might be relevant in designing useful configurations of BSCCO JJ.
