Abstract

In the article we prove that:

1.Form of Intensity of the Moving Charge Electric Field is asymmetrical,

2. Form of the interference field is non-linear,

3. Kinetic energy of a charge moving at the velocity of v has two different values:

Kinetic energy *against direction of motion* **as wave**

$$T_{kin\,ad} = mc^2[ln\,|1+v/c|- (v/c)/(1+v/c)]$$

Kinetic energy *in direction of motion* **as particle**

$$T_{kin\,id} = mc^2[ln\,|1-v/c|+ (v/c)/(1-v/c)]$$

*An electron moving at a speed $v_e= 0,003c$ creates spectral line **Hα**. Accurate electron speeds are given in the table in this article. Confirmation of Doppler´s principle in hydrogen for Balmer line **Hα**.*

Accompanying activity of reaction on movement of stable particles in the transmission medium are waves.
*Stable **electrons** moving with speeds (**0,99 c – c**) creates leptons (**µ–, τ–**), neutrinos (**νe, νµ, ντ**) and bosons **W +, W-, Z** (= **β** electrons). Weak interactions are caused with stable **electrons,** which creates leptons (**µ–, τ–**) = (particles = electrons different speeds), neutrinos **νe, νµ, ντ** (= waves) , bosons **W +, W-, Z** (= particles = **β** electrons moving at nearly the speed of light) and **gamma rays (=**waves of extremely high frequency $>10^{19}$ Hz).*
*Stable particles (**p +, n0, D, He-3, α**) moving with speeds (**0,3 c – 0,99 c**) creates baryons and mesons.*
*The strong interactions are caused with stable particles (**p +, n0, D, He-3, α**), which creates baryons and mesons.*

1. Introduction

Through the work of Max Planck, Albert Einstein, Louis de Broglie, Arthur Compton, Niels Bohr, and many others, current scientific theory holds that all particles also have a wave nature (and vice versa).[1] This phenomenon has been verified not only for elementary particles, but also for compound particles like atoms and even molecules. For macroscopic particles, because of their extremely short wavelengths, wave properties usually cannot be detected.[2] Wave–particle duality is an ongoing conundrum in modern physics. Most physicists accept wave-particle duality as the best explanation for a broad range of observed phenomena; however, it is not without controversy.

Albert Einstein , who, in his search for a Unified Field Theory , did not accept wave-particle duality, wrote: [4]

> This double nature of radiation (and of material corpuscles)...has been interpreted by quantum-mechanics in an ingenious and amazingly successful fashion. This interpretation...appears to me as only a temporary way out...

The pilot wave model, originally developed by Louis de Broglie and further developed by David Bohm into the hidden variable theory proposes that there is no duality, but rather a system exhibits both particle properties and wave properties simultaneously, and particles are guided, in a deterministic fashion, by the pilot wave (or its " quantum potential ") which will direct them to areas of constructive interference in preference to areas of destructive interference . This idea is held by a significant minority within the physics community. [5]

When in this idea we will replace the "quantum potential" by "electromagnetic potential" (or by " interference of electromagnetic waves"), the idea will be acepted large majority of physicists.

In 1900 Max Planck hypothesized that the frequency of light emitted by the black body depended on the frequency of the oscillator that emitted it, and the energy of these oscillators increased linearly with frequency (according to his constant h, where E = hν).

Theoretical Planck´s oscillator we can replace with circulating electron along ellipse around the nucleus of an atom between two Bohr´s energy levels, while electron moving alternately with acceleration and deceleration. This electron really blinks. When an electron moves at the speed of a higher Bohr energy levels (from afnucleus) to lower (towards perinucleus) radiates spectral lines of certain thickness. (real blinks) For example, spectral line Halfa 656.281 + - 1.4 nm.

From the thickness of the spectral lines

we can easily identify the smallest (in afnucleus) and largest (in perinucleus) the speed of the

electron around the nucleus of an atom, taking into account the kinetic energy of the electron

in the direction of movement and against the movement if we know that according to the

Doppler principle is the lowest wavelength (highest frequency) and against the direction of

motion of the electron is a wavelength of the highest (lowest frequency).

$\dfrac{v}{c}$	Front of electron $\left[ln\left|1 - \dfrac{v}{c}\right| + \dfrac{\frac{v}{c}}{1 - \frac{v}{c}}\right]$	Behind of electron $\left[ln\left|1 + \dfrac{v}{c}\right| - \dfrac{\frac{v}{c}}{1 + \frac{v}{c}}\right]$
Electron 0,0027171 It is v/c in the direction of motion (id)	3,704855771252357587814e-6 1,8931773275045679448456131 eV Lambda$_{id}$ (v/c=0,0027171) = hc/E$_{k,id}$ = =654,900051928391151 nm 4,577682611525892171951e+14 Hz 1,8931773275 eV	
Electron 0,0027212 It is v/c against the direction of motion (ad)		3,6890835634754294761e-6 1,885117746 eV Lambda$_{ad}$ (v/c= 0,0027212)=hc/ E$_{k,ad}$ = = 657,69999384 nm

Lambda$_{ad}$ (v/c= 0,0027212042)=hc/ E$_{k,ad}$ = 657,699993842 nm = Lambda$_{ad}$ = c/ f$_{min}$=

= 657,7 nm against the direction of motion of electron, moving with speed v = 0,0027212042c.

Electron is in perinucleum. Frequency 4,577682611526e+14 Hz

Lambda$_{id}$ (v/c=0,002717146) = hc/E$_{k,id}$ =654,9 nm = Lambda$_{id}$ =

=c/ f$_{max}$= 654,9 nm in the direction of motion of electron

moving with speed v = 0,002717146c. Electron is in afnucleum.

Frequency 4,5581945872e+14 Hz.

The wings[16] of spectral line Hα are 1 nm.

(658,68 nm − 657,7 nm =0,98 nm,   654,9 nm − 653,92 nm = 0,98 nm).

Physics in the past formulated at least part of the truth about the physical phenomena.
Some ideas, even if they were doubtful and rejectable, are still valid today:

1. Electron radiates electromagnetic waves if and only if moves with acceleration from the
higher Bohr´s energy levels to a lower. In atom, as a source of electromagnetic waves , them
it then , when it moves from afnucleum to perinucleum along the ellipse . If the electron
moves with decelerated motion, when it absorbs energy , while moving from a lower to a
higher energy level, in the direction from perinukleum to afnucleum along the ellipse with of
very small eccentricity . Eccentricity of the ellipse is maximal, when electron radiates head
of series. Minimal, almost zero, eccentricity corresponds to edge series.
Faulty arguments leveled against classical physics - the electron is moving with acceleration
along of a spiral towards the nucleus - we will find in Beiser[19] 5.7 The failure of classical
physics , p.120 , Fig.5.12 : " Electron in an atom should be according to classical physics,
rapidly converge to the nucleus , because as a result of its acceleration radiates energy."
Because the electron flashes **4,56794e+14** times per second, i.e. emits   energy **4,56794e+14**
times per second and absorbs energy **4,56794 e+14** times per second (for spectral line **Hα**).
Electron creates in the transmission medium, electromagnetic wave   **4,56794 e+14** times per
second and absorbs energy **4,56794e+14**   times per second (for spectral line **Hα**) - Beiser´s
argument is unfounded.
Electron is no oscillator. Atóm resembles to the solar system with the same "planets"
(electrons) and different distances from the nucleus. Electron in an atom not to skip, but
moves continuously with great speed, which increases from the value **0,002717146 c** (in
afnucleum) to **0,0027212042 c** (in perinucleum). Then decreases from the value
0,0027212042 c (in perinucleum) to **0,002717146 c** (in afnucleum) etc.
 Changing the speed of the electron is repeated **9,1358772e+14** times per sec. (spectral lines
Hα).

2. The quantum harmonic oscillator as the quantum-mechanical analog of the classical
Planck´s harmonic oscillator we can replace with circulating electron along ellipse around
the nucleus of an atom between two Bohr´s energy levels, while electron moving alternately
with acceleration and deceleration. Linear harmonic oscillator is only the projection of the
real motion of the electrons along the ellipse in the plane perpendicular to the plane of the
ellipse.
 Linear harmonic oscillator is only the projection of the real motion of the electrons along the
ellipse in the plane perpendicular to the plane of the ellipse.
Or more accurately, is only the projection - of rotating ellipses (Sommerlfeld's ellipses
around perinucleus)   - in a plane perpendicular to the plane of the ellipses.
In quantum mechanics are used so imprecise and imperfect expressions of motion of electrons
around the nucleus.

Definition of particle

The main characteristic of the particle :

Particle as a source exists if and only if repeatedly speeds up and slows down its movement in source along ellipse (when blinks).

Particle as a source, creates in the transmission medium, electromagnetic wave, that spreads in all directions with the velocity c/n,

regardless of the source movement, where n is the refractive index of the transmission medium.

In other words, particle, which is the source, can not become the transmission medium and remain in it.

Particle that is the source, remain in the source.

Definition of waves

The main characteristic of the waves is the energy transfer through a transmission medium.

And no transfer of the substance (= of real particles) from the source to the transmission medium.

Wave exists if and only if there is not a source.

In the case of electromagnetic waves, see **2.1.3 The electromagnetic field. Maswell's equations, p. 28**[3]

electric field intensity E and the magnetic induction B

are both associated with the intensity of a moving charge

$$E_{mov} = E_{still}\left(1-\frac{v}{c}\cos\vartheta\right)^2 \qquad = E_{still} + \text{B} \qquad \text{where} \qquad B = \frac{E_{still}}{c}\left(2+\frac{v}{c}\sin\phi\right)$$

The force acting on the moving electric charge is

$$F = QE_{mov} = QE_{still}\left(1-\frac{v}{c}\cos\vartheta\right)^2 = QE_{still}\left(1+\frac{v}{c}\sin\phi\right)^2 =$$

$$= QE_{still} + QE_{still}\left(2+\frac{v}{c}\sin\phi\right)\frac{v}{c}\sin\phi$$

whereby $-\cos\beta = \sin\phi$

$$F = F_{el} + F_{m} = QE + Q\left(v\times B\right)$$

Neutron, β electron , gamma rays

Gamma rays have frequencies above 10 exahertz (10^{19} Hz), and therefore have energies above 100 keV and wavelength less than 10 picometers, often smaller than an atom. Gamma rays from radioactive decay commonly have energies of a few hundred keV, and almost always less than 10 MeV. The upper limit for such energies is about 20 MeV, and there is effectively no lower limit (they are sometimes classed as x-rays if their frequencies are lower than 10^{19} Hz).

β electron is emitted from the neutron
The Feynman diagram for beta decay of a neutron into a proton , electron , and electron antineutrino via an intermediate heavy W boson.
In the "stable" neutron, electron orbits around the center-of-mass with speed greater than 0,999994c.
If will start beta decay of a neutron, β electron has kinetical energy in direction of motion 80 398 MeV (it is W- boson), proton is moving at a speed 0,023337c, and radiates γ ray.

Planck : 80 398 MeV = h*f , f is frequency circulation electron around center of mass in neutron in center- of- mass coordinate system

Neutron (= Proton and an electron orbiting a common center of mass) Beta decay is mediated by the weak force.

2. Theory

2.1. Form of Intensity of the Moving Charge Electric and Magnetic Field

2.1.1 Intensity of the Moving Charge Electric Field

Let us have a system of coordinates *(x, y, z)* connected with the medium causing propagation of light. Let the electric field intensity in this medium propagate at speed *c* in all directions. It is known from Coulomb's law that intensity of the still standing charge in relation to the

system of coordinates *(x, y, z)* decreases with the square of distance from that charge then represented by hyperboles symmetrical to the charge, illustrated in section as follows:

Fig. 2.1. The intensity of the stillstanding charge

r - distance of the hyperbole point from the beginning

Charge *q* is situated at level *yz* and in the distance of y_q from the beginning in the direction of axis *y*.

Let us now examine what would happen with the form of curves representing the intensity of the electric field, if charge *q* will move in a uniform straight line motion in the direction of the axis *y* at a constant speed *v*. Let's thus join firmly the system of coordinates *(x', y', z')* with the charge *q*, see . Fig. 2.2.

*r* - distance of the hyperbole point from the beginning

Fig. 2.2. The system of coordinates (x', y', z')

Distance r' is measured in direction of axis y' from the charge (or from the beginning O' respectively), while it is valid

$$r'=r-vt \tag{2.1}$$

At the moment $t_0=0$ both systems become identical.

When $t-\Delta t_{id}$, the charge finding itself at the distance of $y_1 = v\left(t - \Delta t_{id}\right)$ would emit intensity propagating at speed c, which at the moment of t would come to point r in time of

$$\Delta t_{id} = \frac{r - y_1}{c} = \frac{r - v\left(t - \Delta t_{id}\right)}{c} \tag{2.2}$$

thus

$$\Delta t_{id} = \frac{r - vt}{c - v} \tag{2.3}$$

The index $_{id}$ means that is the case of propagation of the electric field intensity in direction of the charge motion.

Let the $\oplus_{id}$ be the distance between the position of the charge at the moment of $t - \Delta t_{id}$ (i.e. when the charge has emitted the intensity to point r) and position of the charge at the moment t, when the intensity emitted "has reached" the point r.

At the time of Δt_{id} the charge will cover the distance of

$$\oplus_{id} = v \cdot \Delta t_{id} = \frac{v(r - vt)}{c - v} = \frac{v}{c - v} r' \tag{2.4}$$

This is the distance at which the charge "outrun" the intensity propagated in direction of the charge motion. Consequently the intensity of the moving charge in relation to the system of coordinates *(x, y, z)* will change its form in the respective $\oplus$ of various *r*: it will be deformed (see Fig. 2.3)

Fig. 2.3. The intensity of the moving charge in the direction of the motion E^{id}_{mov}

It is evident that with increasing distance r_i (*i* = 1,2,3,...) the respective "retardation of intensity" $\oplus_{id}$ (r_i) also increases, as can be seen in equation (2.4) . As the intensity of the moving charge in the direction of the motion E^{id}_{mov} at point *r'* and moment *t* equals the intensity of the stillstanding charge at point $\left(r' + \oplus_{id}\right)$ at the moment of intensity emittance $t - \Delta t_{id}$, then:

$$E^{id}_{mov}\left(r'\right) = E_{still}\left(r' + \oplus_{id}\right)$$ (2.5)

From the Coulomb's law:

$$E_{still}\left(r' + \oplus_{id}\right) = const \frac{1}{\left(r' + \oplus_{id}\right)^2}$$ (2.6)

$$E_{still}\left(r'\right) = const \frac{1}{r'^2}$$ (2.7)

r are distances of points of hyperbola from the beginning of the non-dashed system, *r'* are distances of points of hyperbola from the beginning 0' in a dashed system, *r*, *r'* are variables of the same function E_{still}(represented by hyperbolas). In other words, there is distance *r*, that numerically equals $r' + \oplus$ distance. Such distance *r'* numerically equals $r' - \oplus$ distance, both

being variables of the same function E_{still}. For detail refer to (2.6) and (2.7). The issue concerns the same Coulomb's law.

By substituing of (2.5) and (2.4) we get

$$E_{mov}^{id}(r') = const \frac{1}{(r' + \oplus_{id})^2}$$

(2.8)

Then by utilizing (2.3), (2.6) and (2.7) we calculate

$$\frac{E_{mov}^{id}(r')}{E_{still}(r')} = \frac{r'^2}{(r' + \oplus_{id})^2} = \left(1 - \frac{v}{c}\right)^2$$

(2.9)

that is

$$E_{mov}^{id} = E_{still}\left(1 - \frac{v}{c}\right)^2$$

(2.10)

Thus we managed to express the intensity of the moving charge in direction of motion by means of the intensity of the stillstanding charge in the given point. Analogically we express the intensity of the electric field of the moving charge against the direction of motion (indexes $_{ad}$), see Fig. 2.4

Fig. 2.4. The distance $\oplus_{ad}$

The charge moving at the speed of v parallel to the axis y is situated (at the moment t) in the distance of $v.t$ from the axis z.

At the moment $t - \Delta t_{ad}$ the charge, situated in the distance of $y_2 = v(t - \Delta t_{ad})$ will emit the intensity to the point r.

This intensity will reach at the moment t just the point r in time of

$$\Delta t_{ad} = \frac{y_2 - r}{c} = \frac{v(t - \Delta t_{ad}) - r}{c} \tag{2.11}$$

from where

$$\Delta t_{ad} = \frac{vt - r}{c + v} \tag{2.12}$$

$\oplus_{ad}$ is the distance between the position of the charge at the moment $t - \Delta t_{ad}$ i.e. when the charge emitted the intensity to the point r and the position of the charge at the moment t, when the emitted intensity "has reached" the point r.

The charge will cover the distance

$$\oplus_{ad} = v \cdot \Delta t_{ad} = \frac{v}{c + v}(v \cdot t - r) = \frac{-v}{c + v} r' \tag{2.13}$$

at time Δt_{ad}, while $r'<0$ and $\oplus_{ad} > 0$.

This is the distance by which the intensity that propagates in the direction opposite to the movement of the charge, is shifted against the intensity of the stillstanding charge in the direction away from the charge, see Fig. 2.5.

Analogically to equations (2.5) - (2.10) we achieve the following:

$$E_{mov}^{ad}(r') = E_{still}(r' + \oplus_{ad}) \tag{2.14}$$

$$E_{still}(r' + \oplus_{ad}) = \text{const} \frac{1}{(r' + \oplus_{ad})^2} \tag{2.15}$$

$$E_{still}(r') = \text{const} \frac{1}{r'^2} \tag{2.16}$$

$$E_{mov}^{ad}(r') = \text{const} \frac{1}{(r' + \oplus_{ad})^2} \tag{2.17}$$

$$\frac{E_{mov}^{ad}(r')}{E_{still}(r')} = \frac{r'^2}{(r' + \oplus_{ad})^2} = \left(1 + \frac{v}{c}\right)^2 \tag{2.18}$$

$$E_{mov}^{ad} = E_{still}\left(1 + \frac{v}{c}\right)^2 \tag{2.19}$$

The form of intensity for $v=0.5c$ see Fig. 2.6.

Fig. 2.5. The intensity of the electric field by means of the moving charge against the direction of motion E^{ad}

Fig. 2.6. The form of intensity for $v = 0.5c$

The equations (2.10) and (2.19) are placeable by common equation

$$E_{mov} = E_{still}\left(1 - \frac{v}{c}\cos\vartheta\right)^2 \tag{2.20}$$

where ϑ is the angle between the direction of the charge motion (the speed v) and the direction of propagation of intensity.

At level xy, the section of the intensity hyperboloid is, for the stillstanding charge, the circle with its centre in the charge, for the moving charge it is the case of all types of Pascal's screw

s2.10. tocks with the charge at the beginning of the coordinates, see Fig. 2.7, Fig. 2.8, Fig.2.9, and Fig. 2.10.

$$v = 0.3c$$

$$\frac{v}{c} < 0.5$$

$$v = 0.6c$$

$$0.5 < \frac{v}{c} < 1$$

Fig. 2.7, 2.8. At level *(x, y)* section of the "hyperoloid" of the intensity for various speeds of the moving charge have a shape of all types of Pascal's screw stocks with charge at the beginning of the coordinates
Fig. 2.9, 2.10. At level *(x, y)* section of the "hyperoloid" of the intensity for various speeds of the moving charge have a shape of all types of Pascal's screw stocks with charge at the beginning of the coordinates
2.1.2 Kaufmann's Experiment

In the period from 1901 to 1906, Kaufmann wrote a number of works, the most coherent of them seems to be concerning experimental evidence of "the changeability of mass with speed". We shall revalue his experiment and will prove - on the basis of the theory given in the preceeding section 2.1.2 - the subject is the influence of intensity of the moving charge on the magnitude of the deviation of influence of intensity of the moving charge on the magnitude of the deviation of beta-rays in the crossed electromagnetic field, and not the changeability of mass with speed.

The attempt is done through a short correct description for sake of qualitative examination of the experiment, utilising some of the measured and calculated values given by Kaufmann in [8]

Beta-rays from Ra source, moving at speed $v \in < 0.48c; 0.99c >$ are simultaneously deflected in the crossed electric and magnetic field, see diagram in Fig. 2.11.
Fig. 2.11. Kaufmann's Experiment - diagram

The device is situated in the evacuated glass vessel. The rays go out from the Ra source, pass the electric screen and create a small spot on a photographic plate.

When the electric field will be created on the condenser plates PP', the additional stripe in the y- direction will arise apart from the non-diverting middle spot close to 0 (consisting of gamma and little diverting $\alpha - rays$).

When the entire device is situated between the poles of the U-shaped magnet (with the electric field switched off), the stripe will arise in the direction of the axis z.

While at the magnetic field we have the movement of electrons along circles expressed in the following equations

$$(x - S_x)^2 + (z - S_z)^2 = r^2 \tag{2.21*}$$

$$S_x = 1.0979 \text{ cm}$$
$$S_{z1} = 65.0608 \text{ cm}$$
$$S_{z2} = 5.8505 \text{ cm}$$
$$r_1 = 65.0684 \text{ cm}$$
were $r_2 = 5.9348 \text{ cm}$

in the electric field we first have the movement along straight line

$$y = -x \operatorname{tg} \beta \tag{2.22*}$$

- electrons are emitted from the source under the angles $\beta \in \langle 1°35', 5° \rangle$ then they move between the condenser plates along the parabola

$$y = (x - 0.246)^2 \frac{e}{m} \frac{E}{2v_0^2 \cos^2 \beta} - x \operatorname{tg} \beta \tag{2.23*}$$

then again along the straight line

$$y = 1.969 \cdot \frac{0.246}{0.270} \operatorname{tg} \beta \tag{2.24*}$$

The points of intersection of straight lines (2.24*) with the level of the photographic spot $x = x'^2 = 3.969$ will give us the deviation y.

The values E used in the calculations

$$E = 205.5 \cdot 10^{10} \quad 328 \cdot 10^{10} \quad 409.5 \cdot 10^{10} \quad (\text{for } v = 0.48c) \tag{2.25*}$$

would give, after substitued into (2.23*) and (2.24*) the deviations $y = 0.2363 \quad 0.3873 \quad 0.4985$ which are almost four times bigger as those acquired (y_b) by Kaufmann.

Considering out theory on $E_{mov}^{id,ad}$ and the values (2.25*) be multiplied by $\left(1 - \frac{v}{c}\right)^2$ we achieve deviations identical with the results of Kaufmann's experiment, see table 1. Thus the theory under 2.1. concerning the intensity of the moving charge of the electric field may be regarded experimentally confirmed.

Table 1.

	1631 V	2603 V	3250 V

y_T-theoretical value (our new theory): $y_T \sim y_\delta$			

---

[8] KAUFMANN, W.: Annalen der Physik, Vierte Folge, Band 19, Leipzig 1906, Verlag von Johann Ambrosius Barth, page 487-552

Kinetic energy of electron (proton) $T_{kin\ id} = mc^2 [ln |1-v/c| + (v/c) / (1-v/c)]$ in direction of motion of electron (proton), where v is velocity of electron (proton) and m is mass of electron (proton)[2]. It's own kinetic energy of the electron (proton).

Kinetic energy of electron (proton) $T_{kin\ ad} = mc^2 [ln |1+v/c| - (v/c) / (1+v/c)]$ against direction of motion of electron (proton), where v is velocity of electron (proton) and m is mass of electron (proton. Represents the wave energy, which creates electron (proton) in transmision medium.

Electron (proton) as a source exists if and only if repeatedly speeds up and slows down its movement in source along ellipse (when blinks).

Electron (proton) as a source, creates in the transmission medium, electromagnetic wave, that spreads in all directions with the velocity c / n,

regardless of the source movement, where n is the refractive index of the transmission medium.

In other words, electron (proton), which is the source, can not be a transmission medium and remain in it.

The main characteristic of the waves is the energy transfer through a transmission medium.

And no transfer of the substance (= of real electron,proton) from the source to the transmission medium.

Wave exists if and only if there is not a source.

In the case of electromagnetic waves, see

2.1.3 The electromagnetic field. Maswell's equations, p. 28[2] electric field intensity E and the magnetic induction B are both associated with the intensity of a moving charge

$$E_{mov} = E_{still}\left(1 - \frac{v}{c}\cos\vartheta\right)^2 = E_{still} + B \qquad \text{where} \qquad B = \frac{E_{still}}{c}\left(2 + \frac{v}{c}\sin\phi\right)$$

The force acting on the moving electric charge is

$$F = QE_{\text{mov}} = QE_{\text{still}}\left(1-\frac{v}{c}\cos\vartheta\right)^2 = QE_{\text{still}}\left(1+\frac{v}{c}\sin\phi\right)^2 =$$

$$= QE_{\text{still}} + QE_{\text{still}}\left(2+\frac{v}{c}\sin\phi\right)\frac{v}{c}\sin\phi$$

whereby $-\cos\beta = \sin\phi$

$$F = F_{\text{el}} + F_{\text{m}} = QE + Q(v \times B)$$

What is the relationship Lorentz derived from the asymmetrical form of the intensity of the moving charge. To derive it we do not need Lorentz's transformations equations, that is we do not need SPACE-TIME. We do not need local time, or covariant equations or physical simultaneity definition or invariant interval. In other words, in physics we do not need Einstein's theory of relativity. From the asymmetrical form of the intensity of the moving charge we can derive Gauss law, Faraday's law and derive the 4th Maxwell's equation, by a Maxwell thinks up and not derived !

The electromagnetic field. Maswell's equations. (Cited from [2] pages 27 – 30):

„Let us take the equation (2.20) in the vector form:

$$E_{\text{mov}} = E_{\text{still}}\left(1-\frac{v}{c}\cos\vartheta\right)^2 \tag{2.21}$$

The force acting on the moving electric charge is

$$F = QE_{\text{mov}} = QE_{\text{still}}\left(1-\frac{v}{c}\cos\vartheta\right)^2 = QE_{\text{still}}\left(1+\frac{v}{c}\sin\phi\right)^2 =$$

$$= QE_{\text{still}} + QE_{\text{still}}\left(2+\frac{v}{c}\sin\phi\right)\frac{v}{c}\sin\phi \tag{2.22}$$

whereby $-\cos\beta = \sin\phi$

It is known, in line with the classical theory, that a magnetic field is created by the moving charges and electric currents. The result is that the moving charge creates its own magnetic field of induction B_q. It continues in this field in motion. According to Lorentz, the force acting on the moving charge in the electromagnetic field at speed v in the magnetic field of induction B and in the electric field of the following intensity E it is valid:

$$F = F_{\text{el}} + F_{\text{m}} = QE + Q(v \times B) \tag{2.23}$$

Let us compare the equations (2.22) and (2.23) .

Intensity E of the electric field according to Lorentz equals to our intensity E_{still}.

As the forces acting on the acting on the moving charge are equal, it must be valid

$$E_{still}\left(2+\frac{v}{c}\sin\phi\right)\frac{v}{c}\sin\phi=v\times B \tag{2.24}$$

With regard to the fact that both the direction E_{still} and the direction of the vector $v\times B$ are identical, for the absolute values it is possible to write

$$E_{still}\left(2+\frac{v}{c}\sin\phi\right)\frac{v}{c}\sin\phi=v\cdot B\cdot\sin\phi$$

i.e.

$$B=\frac{E_{still}}{c}\left(2+\frac{v}{c}\sin\phi\right) \tag{2.25}$$

This means that the charge moving at speed v creates around itself its own magnetic field of

the following induction: $\qquad B=\frac{E_{still}}{c}\left(2+\frac{v}{c}\sin\phi\right)$

while the vectorial equation is in force

$$v\times B=E_{mov}-E_{still} \tag{2.26}$$

Where from

$$E_{mov}=E_{still}+v\times B \tag{2.27}$$

The intensity of moving charge comprises in itself also the magnetic field induction B created by the charge moving at speed v.

Based on (2.27) Maxwell's equations which are always valid (not only in static) acquires form:

1.

$$\nabla E_{mov}=\nabla(E_{still}+v\times B)=\nabla E_{still}+\nabla(v\times B)=\frac{\rho}{\varepsilon_0} \qquad (\text{...Gauss law}) \tag{2.28}$$

$$\text{because}\qquad \nabla(v\times B)=0 \tag{2.29}$$

2. $$\qquad\qquad\qquad \nabla B=0 \qquad\qquad \text{there are no magnetic charges} \tag{2.30}$$

3. $$\qquad \nabla\times E_{mov}=\nabla\times[E_{still}+(v\times B)]=\nabla\times E_{still}+\nabla\times(v\times B)$$

$$\text{becose in the statics}\quad \nabla\times E_{still}=0$$

further $\quad \nabla\times(v\times B)=v(\nabla B)-B(\nabla v)$

We use (2.29) and except of constant it is valid

$$\nabla \cdot v = \frac{\partial}{\partial t} \qquad\qquad (2.31)$$

Then

$$\nabla \times E_{mov} = -\frac{\partial B}{\partial t} \qquad\qquad (\text{...Faraday's law}) \qquad\qquad (2.32)$$

4. Amper's law in statics

$$c^2 \nabla \times B_{stat} = \frac{j}{\varepsilon_0} \qquad\qquad (2.33)$$

$$B_{dyn} = B_{stat} + \left(B_{dyn} - B_{stat}\right) = B_{stat} + B_Q$$

Total magnetic field

$$B_{dyn} = B_{stat} + B_Q \qquad\qquad (2.34)$$

where

$$B_Q = B_{dyn} - B_{stat} \qquad\qquad (2.35)$$

Let's calculate $\qquad c^2 \nabla \times B_{dyn} = c^2 \nabla \times B_{stat} + c^2 \nabla \times B_Q$

For own magnetic field B_Q of the charge moving at speed v it is possible to write:

$$c^2 B_Q = \left(v \times B_Q\right) \times v \qquad\qquad (2.36)$$

$$\nabla \times \left[\left(v \times B_Q\right) \times v\right] = \left(v \times B_Q\right)\left(\nabla v\right) - v\left[\nabla\left(v \times B_Q\right)\right] =$$

$$= \frac{\partial\left(v \times B_Q\right)}{\partial t} = \frac{\partial\left(E_{mov} - E_{still}\right)}{\partial t} = \frac{\partial E_{mov}}{\partial t}$$

because $\quad \nabla\left(v \times B\right) = 0 \quad , \quad \nabla \cdot v = \frac{\partial}{\partial t} \quad , \quad E_{mov} = E_{still} + v \times B$

and because $\quad \dfrac{\partial E_{still}}{\partial t} = 0 \qquad\qquad (2.37)$

i.e. $\quad c^2 \nabla \times B_{dyn} = \dfrac{j}{\varepsilon_0} + \dfrac{\partial E_{mov}}{\partial t} \qquad\qquad (2.38)$

what represents the 4th Maxwell's equation".

Consequence : Form of Intensity of the Moving Charge Electric Field is asymmetrical.

2.2 The non-linear form of the interference field

Until recently it has been assumed that the shape of the interference field is "linear". The corresponding fraction of the shift of the interference fringes is directly proportional to the corresponding part of the wave length. If, for example, the distance of two interference fringes

is divided into 100 divisions and the shift of 23 divisions is detected, we thus assume that the change occured over a length of $\dfrac{23}{100} \cdot \dfrac{\lambda}{2}$.

In other words, the shift of the fringes is considered to be equivalent to the change of length. This view corresponds to the linear form of the interference field, see Fig. 2.12.
Fig. 2.12. The "linear" form of the interference field

What justifies us our assumption that the interference field is linear? Is the assumption correct?

In physics we are used to picture the experimental results through curves which are not "saw-tooth" as is the case with the linear interference field, but which have a nicely rounded shape. Let us replace the "saw-tooth" linear interference field by some rounded non-linear interference field.

Let us choose sinusoides or semi-circles instead of the sawtooth abscissas. In case of semi-circles according to Fig. 2.13 we get:
Fig. 2.13. The non-linear form of the interference field

in the 3rd quadrant:
$$y^2 + \left(\frac{\Delta l}{\lambda}\right)^2 = 0.5^2$$
, as

$$\kappa - 0.5 = y \qquad \kappa^2 - \kappa + 0.5^2 + \left(\frac{\Delta l}{\lambda}\right)^2 = 0.5^2$$

$$\kappa_{12} = 0.5 \pm \sqrt{\left[0.25 - \left(\frac{\Delta l}{\lambda}\right)^2\right]} \qquad\qquad (2.46)$$

In the shifted 1st quadrant

$$(\kappa - 0.5)^2 + \left(\frac{\Delta l}{\lambda} + 1\right)^2 = 0.5^2$$

$$\kappa_{12} = 0.5 \pm \sqrt{\left[0.25 - \left(\frac{\Delta l}{\lambda} + 1\right)^2\right]} \qquad\qquad (2.47)$$

2.2.1. Fizeau's Experiment

Let us revalue the results of the Fizeau's experiment from the aspect of non-linear interference field. Fizeau [6] used light of wave length $\lambda = 0.526\,\mu m$, two tubes, each L=1.4875 m long in which water flowed at speed u=7.059 m/s. As the experiment is generally known, we shall not describe it in detail. We shall only reassess its results.

The relation $\dfrac{\Delta l}{\lambda} = 0.4103$ corresponds to equal values of the shift of fringe κ supposing the interference field to be linear. In reality the experimentally observed values from the interval ranged from 0.167 to 0.307 in the average of $\bar{\kappa} = 0.23016$. That was explained by Fresnel's theory of partial drag of ether with the drag coefficient α. Should we consider the non-linear form of the interference field, then according to (2.46) we get

$$\kappa = 0.5 \pm \sqrt{\left(0.25 - 0.41^2\right)} = 0.22$$

which is in line with the experimentally observed mean value $\bar{\kappa}$. We do not need any coefficient α. Fizeau's experiment confirms also that the interference field has a non-linear form.

2.2.2. Harres's Experiment

Harres [7] used two wavelengths of light

$$\lambda_{625} = 0.625\,\mu m \qquad \lambda_{535} = 0.535\,\mu m$$

which were passing through ten firmly fastened prisms in a rotating apparatus at speed 400-600 revolutions/min. According to [7], if the drag coefficient $x = \alpha$ is not included

$$\frac{\Delta l}{\lambda} = \frac{200\,n^2\pi}{z_m\lambda c}\,0.20409 + \frac{200\,\pi}{z_m\lambda c}\,0.00188$$

were $z_m = 0.99727z$, z - is the number of sideral time seconds required by the apparatus to make 50 revolutions.

After the arrangement

$$\frac{\Delta l}{\lambda_{625}} = \frac{1.70148214}{z} \tag{2.48}$$

$$\frac{\Delta l}{\lambda_{535}} = \frac{2.00028242}{z} \tag{2.49}$$

The average value $\bar{z} = 5.11$ (tab. 1) after substitution in (2.48) gives

$$\frac{\Delta l}{\lambda_{625}} = 0.333$$

Substituing $\dfrac{\Delta l}{\lambda}$ to (2.46) we get

$$\kappa = 0.5 - 0.3755 = 0.1245$$

According to the experiment $\kappa_{Harres} = 0.132$ is again in line with the theory of the non-linear interference field. The comparison of Harres's experimental values that do not include the drag coefficient α with both linear and non-linear form of the interference field, as well as the results of Fizeau's experiment, are shown in Fig. 2.14.-2.21.

Fig. 2.14.-2.21. The comparison of Harre's experimental values which do not comprise the drag coefficient with both linear and non-linear form of the interference field, as well as the results of Fizeau's experiment.
Fig. 2.14. Fizeau's experiment   [6] p. 392

Fig. 2.15. [7] Tab. 1., 1. Reihe

$$\frac{\Delta l}{\lambda_{625}} = \frac{1.70148214}{z}$$
Fig. 2.16. [7] Tab. 1., 2. Reihe

$$\frac{\Delta l}{\lambda_{625}} = \frac{1.70148214}{z}$$
Fig. 2.17. [7] Tab. 1., 3. Reihe

$$\frac{\Delta l}{\lambda_{625}} = \frac{1.70148214}{z}$$
Fig. 2.18. [7] Tab. 1., 4. Reihe

$$\frac{\Delta l}{\lambda_{535}} = \frac{2.00028242}{z}$$
Fig. 2.19. [7] Tab. 2., 1. Reihe

$$\frac{\Delta l}{\lambda_{535}} = \frac{2.00028242}{z}$$
Fig. 2.20. [7] Tab. 2., 2. Reihe

$$\frac{\Delta l}{\lambda_{535}} = \frac{2.00028242}{z}$$
Fig. 2.21. [7] Tab. 2., 3. Reihe

This is simultaneously proves that the drag coefficient always equals one and the interference field has a non-linear form. Consequently, the interference fields are identical only for the shift of the interference fringes about 0 and/or 100 and 50 divisions.

Consequence :   Form of the interference field is non-linear: (from [2] pages 34 – 39).

3. Calculation of the kinetic energy T_{kin} of a body moving at the velocity of v

For the sake of simplicity let us consider for instance the gravitational field of the Earth. Analogically to (2.20) for the intensity of the gravitational field one could write:

$$g_{mov} = g_{still}\left(1 - \frac{v}{c}\cos\vartheta\right)^2 \qquad (3.1)$$

Let us consider the physical processes in which kinetic energy is transformed into potential one and potential energy is transformed into kinetic one. There is a state in which the potential energy equals total energy of the body (while the kinetic energy equals zero) and the state in which kinetic energy equals the total energy of the body (while the potential energy equals zero). These extreme will help us to calculate the kinetic energy of body. For the potential energy we have

$$dW_p = mg_{still}\,dh \qquad (3.2)$$

By integrating and utilizing of the relation (3.1) we have

$$T_{kin} = \int dW_p = \int_0^h mg_{still}\,dh = \int_0^h m\frac{g_{mov}}{\left(1 - \frac{v}{c}\cos\vartheta\right)^2}\,dh$$

By substituting $g_{mov} = \dfrac{dv}{dt}$, $\dfrac{dh}{dt} = v$

we get

$$T_{kin} = m\int_0^v \frac{v\,dv}{\left(1 - \frac{v}{c}\cos\vartheta\right)^2} \qquad (3.3)$$

Solving by substitution $1 - \dfrac{v}{c}\cos\vartheta = z$

we get

$$T_{kin} = \frac{mc^2}{\cos^2\vartheta}\left[\ln\left|1 - \frac{v}{c}\cos\vartheta\right| + \frac{\frac{v}{c}\cos\vartheta}{1 - \frac{v}{c}\cos\vartheta}\right] \qquad (3.4)$$

while ϑ isn't $\dfrac{\pi}{2}, \dfrac{3\pi}{2}$

For $\vartheta = 0°$ we have the kinetic energy in the direction of motion

$$T_{kin_{ad}} = mc^2 \left[\ln\left|1 - \frac{v}{c}\right| + \frac{\frac{v}{c}}{1 - \frac{v}{c}} \right]$$ (3.5)

For $\vartheta = 180°$ we have the kinetic energy against the direction of motion

$$T_{kin_{ad}} = mc^2 \left[\ln\left|1 + \frac{v}{c}\right| - \frac{\frac{v}{c}}{1 + \frac{v}{c}} \right]$$ (3.6)

If $0 < \frac{v}{c} = x << 1$ (i.e. $v << c$)

utilizing the series $\ln(1 \pm x)$ $(1 \pm x)^{-1}$

the equations (3.5) and (3.6) will be changed in the equation $T_{kin_{ad}} = T_{kin_{ad}} = \frac{1}{2}mv^2$

complying with the Newton's mechanics. In Table 2 the values of the kinetic energy are

$T_{kin_{ad}}$, $T_{kin_{ad}}$. The total energy according to Einstein $\frac{m_0 c^2}{\sqrt{1 - \frac{v^2}{c^2}}}$.

Table 2. Calculation of the kinetic energy T$_{kin}$ of a body moving at the velocity of v according to Einstein and according to Vlcek

v/c	Vlcek´s theory - **kinetic energy** against direction of motion as wave $T_{kin\ ad} =$ $mc^2[ln\ |1+v/c|- (v/c)/(1+v/c)]$	Vlcek´s theory – **kinetic energy** in direction of motion as particle $T_{kin\ id} =$ $mc^2[ln\ |1-v/c|+ (v/c)/(1-v/c)]$	Vlcek´s theory $m = m_0 = const$ $(T_{k\ ad} + T_{k\ id})/2$	Einstein´s theory $T_{kin} =$ $mc^2 - m_0\ c^2$

Direct measurement of the speed in the experiments Kirchner[3], [4], Perry, Chaffee [5]
For v/c = 0.08-0.27 can not yet prove the validity of Vlcek's theory[2] or Einstein's theory[1].

Consequence.
The main differences between Einstein's theory [1] and the latest knowledge [2] are:

1.Form of Intensity of the Moving Charge Electric Field is asymmetrical,

2. Form of the interference field is non-linear,

3. Kinetic energy of a charge moving at the velocity of v has two different values:

Kinetic energy of charge

Tkin id =mc2 [ln |1-v/c|+ (v/c) / (1-v/c)]   in direction of motion of charge

where v is velocity of charge.

Kinetic energy of charge

Tkin ad = mc2 [ln |1+v/c|- (v/c) / (1+v/c)]   against direction of motion of charge

 where v is velocity of charge.

These are the main differences between Einstein's theory and the latest knowledge.

 For example:

Lambda hyperon 2286.46 MeV in direction of motion and pion π0 : 134.9766(6) MeV against direction of motion are in the proton at speed of proton v = 0,8022863362c

hyperon Chi c (2645)+ 2646.6MeV in direction of motion and pion π_0 : 139.57018(35) MeV against direction of motion are in the proton at speed of proton v = 0,819183027c

hyperon 6,165 GeV in direction of motion and meson K- 493.7 MeV against direction of motion are in the alpha particle at speed of alpha particle v = 0,7533c

Electron in direction of motion, electron neutrino against direction of motion are in the electron at speed of electron :
from v= 0.1c to v= 0.9 c

Muon in direction of motion, muon neutrino against direction of motion are in the electron at speed of electron : v = 0.995308032046c

Tauon in direction of motion, tauon neutrino against direction of motion are in the electron at speed of electron : v = 0.99971316674c

W + - boson in direction of motion and neutrino against direction of motion are in the electron at speed of electron : v = 0.99999364465781184c

Z boson in direction of motion and neutrino against direction of motion are in the electron at speed of electron : v = 0.999994396590953c

For example:

Lambda hyperon 2286.46 MeV in direction of motion and pion $\pi0$: 134.9766(6) MeV against direction of motion are in the proton at speed of proton v = 0,8022863362c

hyperon Chi c (2645)+ 2646.6MeV in direction of motion and pion π_0 : 139.57018(35) MeV against direction of motion are in the proton at speed of proton v = 0,819183027c

hyperon 6,165 GeV in direction of motion and meson K- 493.7 MeV against direction of motion are in the alpha particle at speed of alpha particle v = 0,7533c

Electron in direction of motion, electron neutrino against direction of motion are in the electron at speed of electron :
from v= 0.1c to v= 0.9 c

Muon in direction of motion, muon neutrino against direction of motion are in the electron at speed of electron : v = 0.995308032046c

Tauon in direction of motion, tauon neutrino against direction of motion are in the electron at speed of electron : v = 0.99971316674c

W + - boson in direction of motion and neutrino against direction of motion are in the electron at speed of electron : v = 0.99999364465781184c

Z boson in direction of motion and neutrino against direction of motion are in the electron at speed of electron : v = 0.999994396590953c

See you please Decay modes in
