

A Partial Proof of Carmichael Conjecture

Neelabh Deka

Abstract- In this note, we shall briefly survey The Carmichael Conjecture and give a partial proof.

1. Introduction

This note is divided into three sections, this section is a brief introduction of Euler phi function (or Euler totient function).

Definition -Euler 's function $\phi(n)$ is defined for natural 'n' as the number of positive integers less than or equal to 'n' and coprime to 'n'. It holds that

$$\phi(n) = n \left(1 - \frac{1}{p_1}\right) \dots \left(1 - \frac{1}{p_k}\right)$$

where $n = p_1^{a_1} \dots p_k^{a_k}$ is the factorization into primes.

In 1907 Robert Carmichael stated that, For every n there is at least one other integer $m \neq n$ such that $\phi(m) = \phi(n)$.

2.PROOF

Suppose n is an odd integer then $n = P_1^{a_1} \dots P_k^{a_k}$, here all P_1, \dots, P_k are odd primes.

$$\begin{aligned}
 \text{So } \phi(n) &= P_1^{a_1} \dots P_k^{a_k} \left(1 - \frac{1}{P_1}\right) \dots \left(1 - \frac{1}{P_k}\right) \\
 &= 2 \cdot \frac{1}{2} \cdot P_1^{a_1} \dots P_k^{a_k} \left(1 - \frac{1}{P_1}\right) \dots \left(1 - \frac{1}{P_k}\right) \\
 &= 2 \cdot P_1^{a_1} \dots P_k^{a_k} \left(1 - \frac{1}{2}\right) \left(1 - \frac{1}{P_1}\right) \dots \left(1 - \frac{1}{P_k}\right) \\
 &= \phi(2n)
 \end{aligned}$$

Hence if n is odd then $\phi(n) = \phi(2n)$

Now we prove for even n .

The only known Fermat primes are $S = \{3, 5, 17, 257, 65537\}$

Now let $n = 2^p \cdot P_1^{a_1} \dots P_k^{a_k}$, where none of P_1, \dots, P_k belongs to S . So,
 $\phi(n) = 2^{p-1} \cdot P_1^{a_1} \dots P_k^{a_k} \left(1 - \frac{1}{P_1}\right) \dots \left(1 - \frac{1}{P_k}\right)$ ----- (A)

If $p = 1$ then its same as previous, so $p \geq 2$.

Now from (A) we have ,

$$\begin{aligned}
& 2^{p-2} \cdot 2 \cdot 3 \cdot \frac{1}{3} P_1^{a_1} \dots P_k^{a_k} \left(1 - \frac{1}{P_1}\right) \dots \left(1 - \frac{1}{P_k}\right) \\
&= 3 \cdot 2^{p-2} \cdot \frac{2}{3} \cdot P_1^{a_1} \dots P_k^{a_k} \left(1 - \frac{1}{P_1}\right) \dots \left(1 - \frac{1}{P_k}\right) \\
&= 3 \cdot 2^{p-2} \cdot P_1^{a_1} \dots P_k^{a_k} \left(1 - \frac{1}{P_1}\right) \dots \left(1 - \frac{1}{P_k}\right) \left(1 - \frac{1}{3}\right) \\
&= \phi(3 \cdot 2^{p-1} \cdot P_1^{a_1} \dots P_k^{a_k})
\end{aligned}$$

If $\phi(n) = 2^p 3^q P_1^{a_1} \dots P_k^{a_k} \left(1 - \frac{1}{P_1}\right) \dots \left(1 - \frac{1}{P_k}\right)$ and none of P_1, \dots, P_k is equal to 7 then $n = 2^p 3^{q+1} P_1^{a_1} \dots P_k^{a_k}$ or $n = 7 \cdot 2^{p-1} \cdot 3^q \cdot P_1^{a_1} \dots P_k^{a_k}$.

But if one of P_1, \dots, P_k is equal to 7 (and all a_1, \dots, a_k greater than 1) then one of $P_1 - 1, \dots, P_k - 1$ is equal to 6. But $2 \cdot 3 \cdot 6 = 36$; $36 + 1 = 37$ a prime. So we can set 37 as a factor of n .

But if we give similar argument that 37 already exists in P_1, \dots, P_k then we cant take 37 as a factor of n .

In this way we cant get a complete solution when $3^2 = 9$ divides n .

3. So our conjecture becomes, If $n = 9 \cdot 4 \cdot k = 36k$ then there is at least one distinct integer m such that $\phi(m) = \phi(n)$.
