Abstract

In this research investigation, the author has detailed a novel method of finding the next term of a sequence based on Evolution.

Theory

Given any Sequence of the kind,

$$S = \{y_1, y_2, y_3, \dots, y_{n-1}, y_n\}$$

We first write them as

$$S = \left\{ \begin{array}{l} y_1 = {}^N P_{j_1 + \delta_1}, y_2 = {}^N P_{j_2 + \delta_2}, y_3 = {}^N P_{j_3 + \delta_3}, \dots, y_{n-1} = {}^N P_{j_{n-1} + \delta_{n-1}}, \\ y_n = {}^N P_{j_n + \delta_n} \end{array} \right\}$$

where in ${}^N P_{j_1 + \delta_1}$, N is the Order Number of the Higher Order Sequence Of Primes in which the number y_1 is slated,

$(j_1 + \delta_1)$ is the position number of the Prime Metric Basis Element. Here, j_i 's are Positive Integers and $0 < \delta_i < 1$.

For Example,

7 which is the 4th Prime Metric Basis Element of the Standard Primes, the Order [1] of which can be taken to 1. Therefore 7 can be written as 1p_4 . In a similar fashion, 8 can be written as

${}^1P_{4+\left(\frac{8-7}{11-7}\right)}$ where 7 is the nearest previous prime number of 8 and 11 is the next nearest prime number of 8. Here, in the

notation ${}^1P_{4+\left(\frac{8-7}{11-7}\right)}$, we can consider $\left(\frac{8-7}{11-7}\right)$ as the δ , the 4 as

the j and the 1 as the N . We can also denote any number in a similar fashion using Higher Order Primes as well. [1] i.e., $N > 1$.

Given $(j_i + \delta_i)$, a method of calculating the Decimal (Pseudo)

Prime corresponding to $(j_i + \delta_i)$ in ${}^N P_{(j_i + \delta_i)}$.

If δ_i is equal to $\left(\frac{a_1 a_2 a_3 \dots a_{k-1} a_k}{10^k}\right)$ where $0 < a_l < 10$ for $l = 1$ to k , we write

$${}^N P_{(j_i+\delta_i)} = {}^N P_{j_i} + \left\{ \frac{\left(a_1 a_2 a_3 \dots a_{k-1} a_k \right)^{th} \text{ PrimeNumber}}{\left(10^k \right)^{th} \text{ PrimeNumber}} \right\} \left\{ {}^N P_{j_i+1} - {}^N P_{j_i} \right\}$$

of N^{th} Order

of N^{th} Order

Given $\binom{N}{P}$, a method of calculating the Decimal (Pseudo) Position $(j_i + \delta_i)$, i.e., the Prime Metric Basis Element Position corresponding to $\binom{N}{P}$ in the Sequence of N^{th} Order Sequence Of Primes.

We write the given number (Real) say $\frac{a}{b}$ as

$\frac{a}{b} = {}^N P_{j_i} + \frac{c}{d}$ where c, d are some N^{th} Order Primes such that the equation holds roughly.

We then find the positions of c, d along the N^{th} Order Sequence of Primes, say they are l, m .

We then write the Position of $\binom{N}{P}$ as

$$j_i + \delta_i =$$

Prime Basis Position of (c) in the N^{th} Order

$$j_i + \frac{\text{Sequence of Primes}}{\text{Prime Basis Position of (d) in the } N^{th} \text{ Order}} \\ \text{Sequence of Primes}$$

For Simplicity, we can take $N = 1$.

For our representational simplicity, we label our $S = \{y_1, y_2, y_3, \dots, y_{n-1}, y_n\}$ as

$S = \{ {}_1y_1, {}_1y_2, {}_1y_3, \dots, {}_1y_{n-1}, {}_1y_n \}$ where the left south subscript 1 indicates that these numbers are at the level 1 (Base) of the triangle we are going to build.

We now compute the Evolution Orders

$E^{(j+1)y_i} \left({}_jy_i \right) = {}_jy_{(i+1)}$ where $(j+1)y_i$ is the Evolution Order. By Evolution Order, we mean the difference between the Prime Basis Position Number of ${}_jy_{(i+1)}$ (when slated thusly) and the Prime Basis Position Number of ${}_jy_i$ given that we are considering this in $N = 1$. This means that ${}_jy_i$

needs to be evolved $(j+1)y_i$ times to get ${}_jy_{(i+1)}$. Please see [2] for Evolution method. We repeat this process till we get

$E^{(n)y_i} \left({}_{(n-1)}y_i \right) = {}_{(n-1)}y_{(i+1)}$. We now evolve ${}_{(n-1)}y_{(i+1)}$ by one

step using [2] and get $E^1\left(\binom{(n-1)}{y_{(i+1)}}\right)$. Note that $E^{\left\{E^1\left(\binom{(n-1)}{y_{(i+1)}}\right)\right\}}\left(\binom{(n-2)}{y_i}\right) = \binom{(n-2)}{y_{(i+1)}}$.

We repeat this procedure, downwards, repeatedly to find $E^{\left\{(2)}{y_n}\right\}}\left(\binom{(1)}{y_n}\right) = \binom{(1)}{y_{(n+1)}}$. If the Evolution Order $(j+1) y_i$ is

negative, this implies that $j y_i$ needs to be devolved by $(j+1) y_i$ to reach $j y_{(i+1)}$. That is when the Evolution Order is Negative, we need to consider Devolution by the amount of the Evolution Order. We illustrate this with an Example of three terms.

Considering

$S = \{y_1, y_2, y_3\}$ which we write as

$S = \left\{\binom{(1)}{y_1}, \binom{(1)}{y_2}, \binom{(1)}{y_3}\right\}$ for future representational simplicity.

$E^{2 y_1}\left(\binom{(1)}{y_1}\right) = \binom{(1)}{y_2}$, $E^{2 y_2}\left(\binom{(1)}{y_2}\right) = \binom{(1)}{y_3}$. Now, we write

$E^{3 y_1}\left(\binom{(2)}{y_1}\right) = \binom{(2)}{y_2}$. We now evolve $\binom{(2)}{y_1}$ by one step using [2], i.e., perform $E^1\left(\binom{(3)}{y_1}\right)$. And now, we write $E^{\left\{E^1\left(\binom{(3)}{y_1}\right)\right\}}\left(\binom{(2)}{y_2}\right) = \binom{(2)}{y_3}$. Finally, we write, $E^{\left\{(2)}{y_3}\right\}}\left(\binom{(1)}{y_3}\right) = \binom{(1)}{y_4} = y_4$ which is the next term of the sequence $S = \{y_1, y_2, y_3\}$. This method can be used advantageously for forecasting.
