Abstract

In this research investigation, the author has detailed a novel method of finding the next term of a sequence based on Evolution.

Theory

Given any Sequence of the kind,

$$S = \{y_1, y_2, y_3, \ldots\ldots, y_{n-1}, y_n\}$$

We first write them as

$$S = \left\{ \begin{array}{l} y_1 = {}^N p_{j_1+\delta_1}, y_2 = {}^N p_{j_2+\delta_2}, y_3 = {}^N p_{j_3+\delta_3}, \ldots\ldots, y_{n-1} = {}^N p_{j_{n-1}+\delta_{n-1}}, \\ y_n = {}^N p_{j_n+\delta_n} \end{array} \right\}$$

where in ${}^N p_{j_1+\delta_1}$, N is the Order Number of the Higher Order Sequence Of Primes in which the number y_1 is slated,

$\left(j_1+\delta_1\right)$ is the position number of the Prime Metric Basis Element. Here, j_i 's are Positive Integers and $0<\delta_i<1$.

For Example,

7 which is the 4th Prime Metric Basis Element of the Standard Primes, the Order [1] of which can be taken to 1. Therefore 7 can be written as ${}^{1}p_4$. In a similar fashion, 8 can be written as

${}^{1}p_{4+\left(\frac{8-7}{11-7}\right)}$ where 7 is the nearest previous prime number of 8 and 11 is the next nearest prime number of 8. Here, in the notation ${}^{1}p_{4+\left(\frac{8-7}{11-7}\right)}$, we can consider $\left(\frac{8-7}{11-7}\right)$ as the δ, the 4 as the j and the 1 as the N. We can also denote any number in a similar fashion using Higher Order Primes as well. [1] i.e., $N>1$.

Given $\left(j_i+\delta_i\right)$, a method of calculating the Decimal (Pseudo) Prime corresponding to $\left(j_i+\delta_i\right)$ in ${}^{N}p_{(j_i+\delta_i)}$.

If δ_i is equal to $\left(\frac{a_1a_2a_3........a_{k-1}a_k}{10^k}\right)$ where $0<a_l<10$ for $l=1\ to\ k$, we write

$$ {}^{N}p_{(j_i+\delta_i)} = {}^{N}p_{j_i} + \left\{ \frac{(a_1a_2a_3.......a_{k-1}a_k)^{th} \text{ PrimeNumber of } N^{th} \text{ Order}}{(10^k)^{th} \text{ PrimeNumber of } N^{th} \text{ Order}} \right\} \left\{ {}^{N}p_{j_i+1} - {}^{N}p_{j_i} \right\} $$

Given $\left({}^{N}p\right)$, a method of calculating the Decimal (Pseudo) Position $\left(j_i + \delta_i\right)$, i.e., the Prime Metric Basis Element Position corresponding to $\left({}^{N}p\right)$ in the Sequence of N^{th} Order Sequence Of Primes.

We write the given number (Real) say $\frac{a}{b}$ as

$\frac{a}{b} = {}^{N}p_{j_i} + \frac{c}{d}$ where c,d are some N^{th} Order Primes such that the equation holds roughly.

We then find the positions of c,d along the N^{th} Order Sequence of Primes , say they are l,m.

We then write the Position of $\left({}^{N}p\right)$ *as*

$$j_i + \delta_i =$$

$$j_i + \frac{\text{Prime Basis Position of } (c) \text{ in the } N^{th} \text{ Order Sequence of Primes}}{\text{Prime Basis Position of } (d) \text{ in the } N^{th} \text{ Order Sequence of Primes}}$$

For Simplicity, we can take $N=1$.

For our representational simplicity, we label our $S=\{y_1, y_2, y_3, \ldots\ldots, y_{n-1}, y_n\}$ as

$S=\{{}_1y_1, {}_1y_2, {}_1y_3, \ldots\ldots, {}_1y_{n-1}, {}_1y_n\}$ where the left south subscript 1 indicates that these numbers are at the level 1 (Base) of the triangle we are going to build.

We now compute the Evolution Orders

$E^{(j+1)y_i}\left({}_jy_i\right) = {}_jy_{(i+1)}$ where ${}_{(j+1)}y_i$ is the Evolution Order. By Evolution Order, we mean the difference between the Prime Basis Position Number of ${}_jy_{(i+1)}$ (when slated thusly) and the Prime Basis Position Number of ${}_jy_i$ given that we are considering this in $N=1$. This means that ${}_jy_i$ needs to be evolved ${}_{(j+1)}y_i$ times to get ${}_jy_{(i+1)}$. Please see [2] for Evolution method. We repeat this process till we get $E^{(n)y_i}\left({}_{(n-1)}y_i\right) = {}_{(n-1)}y_{(i+1)}$. We now evolve ${}_{(n-1)}y_{(i+1)}$ by one step using [2] and get $E^1\left({}_{(n-1)}y_{(i+1)}\right)$. Note that $E^{\left\{E^1\left({}_{(n-1)}y_{(i+1)}\right)\right\}}\left({}_{(n-2)}y_i\right)={}_{(n-2)}y_{(i+1)}$.

We repeat this procedure, downwards, repeatedly to find $E^{\left\{{}_{(2)}y_n\right\}}\left({}_{(1)}y_n\right)={}_{(1)}y_{(n+1)}$.

We illustrate this with an Example of three terms.

Considering

$S=\{y_1,y_2,y_3\}$ which we write as

$S=\{{}_1y_1,{}_1y_2,{}_1y_3\}$ for future representational simplicity.

$E^{{}_2y_1}\left({}_1y_1\right)={}_1y_2$, $E^{{}_2y_2}\left({}_1y_2\right)={}_1y_3$. Now, we write

$E^{{}_3y_1}\left({}_2y_1\right)={}_2y_2$. We now evolve ${}_3y_1$ by one step using [2], i.e., perform $E^1\left({}_3y_1\right)$. And now, we write $E^{\left\{E^1\left({}_3y_1\right)\right\}}\left({}_2y_2\right)={}_2y_3$. Finally, we write, $E^{\left({}_2y_3\right)}\left({}_1y_3\right)={}_1y_4=y_4$ which is the next term of the sequence $S=\{y_1,y_2,y_3\}$. This method can be used advantageously for forecasting.

Note that $E^1(0)=0$ and $E^1(1)=E^1\left(\frac{2}{2}\right)=\frac{3}{2}$, from [2].
