is there is anything called middle in physics?
for example if you have a particle moving in space and you define the direction it goes it would eother go tilted to the top and tilted to the bottom so if a particle follows a specific direction not top or down then it doesnt change it being in the middle
but doesnt that mean its unchanching in time?how do you measure something in the middle? maybe its absence?
like when you drive a car that deflect slightly as you drive through a straight road with sensors you end up out of the road and no sensor can find you now you are then found be saying that you are absent from the middle the same is for when you drive your cars in the middle of a road and the sensors in both sides of the road dont find you so you know that you are in the middle maybe you need time to know that you are in the middle depending on the place you are driving your car and sensors beside or more importantly the time you are measuing so lets shrink the road onto a point equal to the length and width of your car and make you drive your car on the point of the road which is in a specific time that means that time is change in place you are defined to where you exited the middle by being lost or found lets shrink the road to that point since it all matter it should be equal to the lengh and width of what we are searching for which is you and car maybe a place is length times width time hight time is place for something changing time is change of place for something so we are generally moving this implements that nothing is stationary? if time passes we need to move on so its not nothingness what matter is after its after change in position and change of status!
