

A Theory of Hadron Structure Involving Higher Dimensional Matter

D. G. Grossman
February 15, 2025

Quarks may be made of higher dimensional matter. If true, then it follows that all hadrons are made of higher dimensional matter. The conventional thinking about quarks, that they are point particles, has not proved useful over the past 50 years. A more useful idea is that the six known quarks (u, d, s, c, b, t) are made of higher dimensional matter, the dimensions of which are respectively (1, 2, 3, 4, 5, 6), and each are equal to a volume of matter defined by the n-sphere surface volume formula of equal dimension. This gives theorists a mathematical handle, with which quarks and hadrons can be investigated.

Here is a list of the known quarks and their corresponding n-sphere surface volume formulae. In the table below, S_n is short for the surface volume formula of an n-sphere, so, S_2 is short for the surface volume formula of a 2-sphere (the circle). The surface "volume" of a 2-sphere is one dimensional. It's the circumference of the circle. So, take note: The dimension of the surface volume of an n-sphere is always one dimension less than the dimension of the interior volume of the n-sphere.

<u>n-Sphere Dimension</u>	<u>Quark</u>	<u>Surface Volume Formulae (Sn)</u>	<u>Dimension of Quark</u>
2	u - up	$S_2 = 2 \pi^1 r^1$	1
3	d - down	$S_3 = 4 \pi^1 r^2$	2
4	s - strange	$S_4 = 2 \pi^2 r^3$	3
5	c - charm	$S_5 = \frac{8}{3} \pi^2 r^4$	4
6	b - bottom	$S_6 = \pi^3 r^5$	5
7	t - top	$S_7 = \frac{16}{15} \pi^3 r^6$	6

Key to the Investigation Of Hadron Masses

The key to the investigation of hadron masses with n-sphere surface volumes is the formula ($xS_n h = \text{mass}$), where x is a number, S_n is the surface volume formula of a unit radius n-sphere, and h is Planck's constant's coefficient (6.62607015 J-s). When divided into experimental particle masses (given in units of MeV/c²) that formula will give theoretical masses in units of MeV/c². It has been tested on hundreds of experimentally determined particle masses and has been found to factor many of them convincingly. A case in point is the table of Lambda baryon masses below.

Experimental Masses Factored with n-Sphere Surface Volumes

<u>Factoring</u>	<u>ThrMass</u>	<u>ExpMass</u>	<u>ExpErr</u>	<u>Particle</u>	<u>Formation Quarks</u>
49.5/7 S9h =	1390.9879	1391	1	$\Lambda(1405)$	dddd, cdd, cc
50/7 S9h =	1405.0383	1405.1	1.3/1.0	$\Lambda(1405)$	dddd, cdd, cc
54/7 S9h =	1517.4413	1517.5	0.4	$\Lambda(1520)$	dddd, cdd, cc
56/7 S9h =	1573.6428	1573	25	$\Lambda(1600)$	dddd, cdd, cc
84/7 S9h =	2360.4643	2360	20	$\Lambda(2350)$	dddd, cdd, cc
90/7 S9h =	2529.0689	2530	25	$\Lambda(2585)$	dddd, cdd, cc
92/7 S9h =	2585.2704	2585	45	$\Lambda(2585)$	dddd, cdd, cc

The table shows some experimentally determined Lambda baryon masses, as listed by Particle Data Group on their website, and the corresponding n-sphere surface volume factoring of each. Notice the close agreement between the first three, which have small experimental errors. The last four in the list have much larger experimental errors, but are also very close to their theoretical values. Tables like the one above (mass spectrum tables) can be made for any type of particles, you just have to find the correct dimension of hypersphere surface volume formula (S_n) with which to factor them, which is determined by their "quark content".

Predictive Power of the n-Sphere Factoring Technique

<u>Factoring</u>	<u>ThrMass</u>	<u>ExpMass</u>	<u>ExpErr</u>	<u>Particle</u>	<u>Formation Quarks</u>
50/7 S9h =	1405.0383	1405.1	1.3/1.0	$\Lambda(1405)$	dddd, cdd, cc
51/7 S9h =	1433.1390	Undiscovered			
52/7 S9h =	1461.2398	Undiscovered			
53/7 S9h =	1489.3406	Undiscovered			
54/7 S9h =	1517.4413	1517.5	0.4	$\Lambda(1520)$	dddd, cdd, cc
55/7 S9h =	1545.5421	Undiscovered			
56/7 S9h =	1573.6428	1573	25	$\Lambda(1600)$	dddd, cdd, cc

N-sphere surface volume factoring is a powerful technique for predicting the existence of new particles. The particles in the table above, the ones NOT in bold type, have not yet been discovered, but could be if looked for, and when found, will assuredly have the masses predicted.

Determining the Correct Sn for Factoring from Quark Content

The dimensions of the quarks that have been discovered so far (u, d, s, c, b, t), are assumed to be (1, 2, 3, 4, 5, 6) dimensional respectively, and each has the shape of the surface of the n-sphere which has surface dimension equal to the dimension of the quark. Let's say you want to find some **dddd** pentaquarks among all the particle experimental mass data listed by Particle Data Group. Which dimension n-sphere surface volume formula (which **Sn**) should you use to factor the suspected experimental masses to determine if they are **dddd** pentaquarks or not? The n-sphere surface volume formula for the 'd' quark is $(4 \pi^1 r^2)$, which is the formula for the surface volume of a 3-sphere, **S3**, so multiply that by itself 5 times. You get $(1024 \pi^5 r^{10})$, which has the same π and r powers as the formula for the surface volume of an 11-sphere, so you would use **S11h** to search for **dddd** pentaquarks. Where should you look for **dddd** pentaquarks? Look in Particle Data Group's category called Light Unflavored Mesons between 1235 MeV and 2200 MeV. There are at least 100 of them in that mass range. They're mostly in 32nds of S11h, which is 4.29 MeV.

There Are More Than Six Quarks

Notice that a **dddd** pentaquark is generated from 'd' quarks, which are 2-dimensional, but **dddd** pentaquark matter is 10-dimensional because the surface volume of an 11-sphere is 10-dimensional. Do the 'd' quarks that form the **dddd** pentaquark retain their identity in the fully formed **dddd** pentaquark after it is made? They can't, because they are 2-dimensional, and the pentaquark's matter is 10-dimensional. (So called, **dddd** pentaquarks factor with S11h, which means they are made of 10d matter.)

Current quark theory of particle structure assumes that when a **dddd** pentaquark forms during a collision in an accelerator, the masses of the 'd' quarks just add together (Total Mass = 5d + KE), and the dimension of the collision reaction's product matter remains the same as the dimension of the reactant matter. In higher dimensional quark mass theory the masses of the colliding quarks also add together (Total Mass= 5d + KE), but they also change their dimension, in this case from 2-dimensional matter to 10-dimensional matter. In general, the dimension of the collision reaction's product matter is determined by the dimension of the surface volume formula that results from multiplying together all the surface volume formulae that are associated with each of the reacting quarks. (In the 'dddd' case, multiplying S3 together five times gives you S11, which is 10-dimensional.)

After the **dddd** pentaquark is formed, the 'd' quarks then no longer exist. Their matter has been transformed into 10-dimensional matter. The quarks that actually make up a **dddd** pentaquark are 10-dimensional quarks. How many are there in a **dddd** pentaquark? How much energy is needed to transform a given amount of 2d quark matter to 10d quark matter? These are good research questions that need answers.

So, to say that a **dddd** pentaquark has quark content **dddd** is a misnomer. It would be more correct to say that the five 'd' quarks that make a **dddd** pentaquark are the formation quarks, or genesis quarks of the particle. The quarks inside the particle after it is formed are made of 10-dimensional matter. They currently have no name. I suggest calling them 'q10' as it is the most logical name for them. This discovery of another quark beyond the six currently known begs the question: How many quarks are there?

How Many Quarks Are There?

Theoretically there are an infinite number of quarks - one for each n-sphere surface volume formula from 2 to infinity. How many have been found so far? The conventional wisdom is that there are only six, but examine the table below of some particles and their factorings. Particles with surface dimensions from 4 to 19, except for dimensions 15, and 18, are listed (have been found), which means that quarks of all those dimensions have been found. So if we call the original six quarks (q1, q2, q3, q4, q5, q6), then the new ones found are (q7, q8, q9, q10, q11, q12, q13, q14, q16, q17, and q19). The higher dimension quarks necessarily exist to explain the existence of the higher dimension hadrons.

Examples of Particles Constructed of Higher Dimensional Matter

The mass of the Rho meson, the **r(775)**, factors with **S5h**, (**S5** represents the formula for the surface volume of a 5-sphere) therefore it is composed of 4-dimensional matter, because the surface of a 5-sphere is 4-dimensional.

Likewise, the mass of the Delta baryon, the **D(1232)**, factors with **S6h**, (**S6** represents the formula for the surface volume of a 6-sphere) therefore it is composed of 5-dimensional matter, because the surface of a 6-sphere is 5-dimensional. And so on, down the list.

Conclusions

Hypersphere surface volume factoring of experimental hadron masses shows hadrons are made of higher dimensional matter. Hadrons comprised of matter from dimensions 4 to 19 have been found. That implies that there has to be more than six quarks, because the dimension of a hadron's matter is the same dimension as the matter in the quarks that comprise it, and the known quarks are only of dimensions 1 through 6.

Also, through the use of hypersphere surface volume factoring, it has been deduced that the currently believed quark content of hadrons is incorrect. Current quark content determinations of hadrons are based on the incorrect belief that the quarks inside hadrons are the same quarks (of the same dimension) as the quarks that form the hadron, and the same dimension as the quarks found in its decay products. That reasoning is incorrect. All current hadron quark content assignments that have been analysed so far with hypersphere surface volume factoring, shows that the currently believed quark content of the hadrons is incorrect.

Also, all hadrons factored so far, have been found to be of a single dimension of matter. Mixed dimension hadrons, such as 'uds', or 'cb', have not been found. It seems that a hadron can be formed from a mixed quark collision reaction, but the resulting hadron has only a single dimension of matter (i.e. only a single dimension of quarks).

More Examples and Appendices

More examples of higher dimensional hadrons follows, from dimension 4 to 18. Also, there are four appendices of useful information.
