

A Theory of Hadron Structure Involving Higher Dimensional Matter

D. G. Grossman
February 28, 2025

Quarks may be made of higher dimensional matter. If true, then it follows that all hadrons are made of higher dimensional matter. The conventional thinking about quarks, that they are point particles, has not proven useful over the past 50 years. A more useful idea is that the six known quarks (u, d, s, c, b, t) are made of higher dimensional matter, the dimensions of which are respectively (1, 2, 3, 4, 5, 6), and each are equal to a volume of matter defined by the n-sphere surface volume formula of equal dimension. This gives theorists a mathematical handle, with which quarks and hadrons can be investigated.

Here is a list of the known quarks and their corresponding n-sphere surface volume formulae. In the table below, Sn is short for the surface volume formula of an n-sphere, so, S2 is short for the surface volume formula of a 2-sphere (the circle). The surface "volume" of a 2-sphere is one dimensional. It's the circumference of the circle. So, take note: The dimension of the surface volume of an n-sphere is always one dimension less than the dimension of the interior volume of the n-sphere.

<u>n-Sphere Dimension</u>	<u>Quark</u>	<u>Surface Volume Formulae (Sn)</u>	<u>Dimension of Quark</u>
2	u - up	S2 = $2 \pi^1 r^1$	1
3	d - down	S3 = $4 \pi^1 r^2$	2
4	s - strange	S4 = $2 \pi^2 r^3$	3
5	c - charm	S5 = $8/3 \pi^2 r^4$	4
6	b - bottom	S6 = $\pi^3 r^5$	5
7	t - top	S7 = $16/15 \pi^3 r^6$	6

Key to the Investigation Of Hadron Masses

The key to the investigation of hadron masses with n-sphere surface volumes is the formula ($xS_n h = \text{mass}$), where **x** is a number, **Sn** is the surface volume formula of a unit radius n-sphere, and **h** is the same as Planck's constant's coefficient, but has different units. It has units of MeV/c², not J-s. In $xS_n h$, **h** = 6.62607015 MeV/c². (See the derivation on page 4). When divided into experimental particle masses (given in units of MeV/c²) the result will be an integer, or an integer and a fraction, if the hadron's matter is of the same dimension as the factoring unit's dimension. It has been tested on hundreds of experimentally determined particle masses and has been found to factor many of them convincingly. A case in point is the table of Lambda baryon masses below.

Experimental Masses Factored with n-Sphere Surface Volumes

<u>Factoring</u>	<u>ThrMass</u>	<u>TM-EM</u>	<u>ExpMass</u>	<u>ExpErr</u>	<u>Particle</u>	<u>Formation Quarks</u>
49.5/7 S9h =	1390.9879	0.0121	1391	1	$\Lambda(1405)$	dddd, cdd, cc
50/7 S9h =	1405.0383	0.0617	1405.1	1.3/1.0	$\Lambda(1405)$	dddd, cdd, cc
54/7 S9h =	1517.4413	0.0587	1517.5	0.4	$\Lambda(1520)$	dddd, cdd, cc
56/7 S9h =	1573.6428	0.6428	1573	25	$\Lambda(1600)$	dddd, cdd, cc
84/7 S9h =	2360.4643	0.4643	2360	20	$\Lambda(2350)$	dddd, cdd, cc
90/7 S9h =	2529.0689	0.9311	2530	25	$\Lambda(2585)$	dddd, cdd, cc
92/7 S9h =	2585.2704	0.2704	2585	45	$\Lambda(2585)$	dddd, cdd, cc

The table shows some experimentally determined Lambda baryon masses, as listed by Particle Data Group on their website, and the corresponding n-sphere surface volume factoring of each. Notice the close agreement between ThrMass and ExpMass of the first three. All TM-EM's are within 0.06 MeV of each other. The last four in the list have much larger ExpErr's, but are also very close to their theoretical values. Those TM-EM's are also small. Less than 1.0 MeV. This close agreement between experimental Lambda baryon masses and theoretical masses obtained from hypersphere surface volume factoring is evidence that Lambda baryons are made of higher dimensional matter.

Predictive Power of the n-Sphere Factoring Technique

<u>Factoring</u>	<u>ThrMass</u>	<u>ExpMass</u>	<u>ExpErr</u>	<u>Particle</u>	<u>Formation Quarks</u>
50/7 S9h =	1405.0383	1405.1	1.3/1.0	$\Lambda(1405)$	dddd, cdd, cc
51/7 S9h =	1433.1390	Undiscovered			
52/7 S9h =	1461.2398	Undiscovered			
53/7 S9h =	1489.3406	Undiscovered			
54/7 S9h =	1517.4413	1517.5	0.4	$\Lambda(1520)$	dddd, cdd, cc
55/7 S9h =	1545.5421	Undiscovered			
56/7 S9h =	1573.6428	1573	25	$\Lambda(1600)$	dddd, cdd, cc

N-sphere surface volume factoring is a powerful technique for predicting the existence of new particles. The particles in the table above, the ones NOT in bold type, have not yet been discovered, but could be if looked for, and when found, will assuredly have the masses predicted.

Determining the Correct Sn for Factoring from Quark Content

The dimensions of the quarks that have been discovered so far (u, d, s, c, b, t), are assumed to be (1, 2, 3, 4, 5, 6) dimensional respectively, and each has the shape of *the surface of the n-sphere* which has surface dimension equal to the dimension of the quark. Let's say you want to find some **dddd** pentaquarks among all the particle experimental mass data listed by *Particle Data Group*. Which dimension n-sphere surface volume formula (which **Sn**) should you use to factor the suspected experimental masses to determine if they are **dddd** pentaquarks or not? The n-sphere surface volume formula for the 'd' quark is $(4 \pi^1 r^2)$, which is the formula for the surface volume of a 3-sphere, (**S3**), so multiply that by itself 5 times. You get $(1024 \pi^5 r^{10})$, which has the same π and r powers as the formula for the surface volume of an 11-sphere, so you would use **S11h** to search for **dddd** pentaquarks. Where should you look for **dddd** pentaquarks? Look in *Particle Data Group's* category called *Light Unflavored Mesons* between 1235 MeV and 2200 MeV. There are at least 100 of them in that mass range. They're mostly in 32nds of S11h, which is 4.29 MeV.

There Are More Than Six Quarks

Notice that a **dddd** pentaquark is generated from 'd' quarks, which are 2-dimensional, but **dddd** pentaquark matter is 10-dimensional because the surface volume of an 11-sphere is 10-dimensional. Do the 'd' quarks that form the **dddd** pentaquark retain their identity in the fully formed **dddd** pentaquark after it is made? They can't, because they are 2-dimensional, and the pentaquark's matter is 10-dimensional. (So called, **dddd** pentaquarks factor with S11h, which means they are made of 10d matter.)

Current quark theory of particle structure assumes that when a **dddd** pentaquark forms during a collision in an accelerator, the masses of the 'd' quarks just add together (Total Mass = 5d + KE), and the dimension of the collision reaction's product matter remains the same as the dimension of the reactant matter. In *higher dimension quark mass theory* the masses of the colliding quarks also add together (Total Mass = 5d + KE), but they also change their dimension, in this case from 2-dimensional matter to 10-dimensional matter. In general, the dimension of the collision reaction's product matter is determined by the dimension of the surface volume formula that results from multiplying together all the surface volume formulae that are associated with each of the reacting quarks. (In the 'dddd' case, multiplying S3 together five times gives you S11, which is 10-dimensional.)

After the **dddd** pentaquark is formed, the 'd' quarks then no longer exist. Their matter has been transformed into 10-dimensional matter. The quarks that actually make up a **dddd** pentaquark are 10-dimensional quarks. How many are there in a **dddd** pentaquark? How much energy is needed to transform a given amount of 2d quark matter to 10d quark matter? These are good research questions that need answers.

So, to say that a **dddd** pentaquark has quark content **dddd** is a misnomer. It would be more correct to say that the five 'd' quarks that make a **dddd** pentaquark are the *formation quarks*, or *genesis quarks* of the particle. The quarks inside the particle after it is formed are made of 10-dimensional matter. They currently have no name. I suggest calling them 'q10' as it is the most logical name for them. This discovery of another quark beyond the six currently known begs the question: How many quarks are there?

How Many Quarks Are There?

Theoretically there are an infinite number of quarks - one for each n-sphere surface volume formula from 2 to infinity. How many have been found so far? The conventional wisdom is that there are only six, but examine the table below of some particles and their factorings. Particles with surface dimensions from 4 to 19, except for dimension 18, are listed (have been found), which means that quarks of all those dimensions have been found. So if we call the original six quarks (q1, q2, q3, q4, q5, q6), then the new ones found are (q7, q8, q9, q10, q11, q12, q13, q14, q15, q16, q17, and q19). The higher dimension quarks necessarily exist to explain the existence of the higher dimension hadrons.

The finding of a hadron of a given dimension through hypersphere surface volume factoring means that quarks of that dimension exist.

Conclusions

Hypersphere surface volume factoring of experimental hadron masses shows hadrons are made of higher dimensional matter. Hadrons comprised of matter from dimensions 4 to 19 have been found. That implies that there has to be more than six quarks, because the dimension of a hadron's matter is the same dimension as the matter in the quarks that comprise it, and the known quarks are only of dimensions 1 through 6.

Also, through the use of hypersphere surface volume factoring, it has been deduced that the currently believed quark content of hadrons is incorrect. Current quark content determinations of hadrons are based on the incorrect belief that the quarks inside hadrons are the same quarks (of the same dimension) as the quarks that form the hadron, and the same dimension as the quarks found in its decay products. That reasoning is incorrect. All current hadron quark content assignments that have been analysed so far with hypersphere surface volume factoring, shows that the currently believed quark content of all hadrons is incorrect.

Also, all hadrons factored so far, have been found to be of a single dimension of matter. Mixed dimension hadrons, such as 'uds', or 'cb', have not been found. It seems that a hadron can be formed from a mixed quark collision reaction, but the resulting hadron has only a single dimension of matter (i.e. only a single dimension of quarks).

Derivation of the *Hypersphere Surface Volume* Factoring Formula

$$\mathbf{m}_{\text{MeV}} = \mathbf{h}_{\text{MeV}}(\mathbf{xSn})$$

The HSSV factoring formula, $\mathbf{m} = \mathbf{h}(\mathbf{xSn})$, which is used to discover hadron dimensions and exact masses, can be derived from Planck's Energy-Frequency Relation: $\mathbf{E} = \mathbf{hf}$. The key to the derivation is associating a frequency with a unit of hypervolume. A main benefit of the derivation is that it explains how the 10^{-34} factor was removed from \mathbf{h} , and its units changed from J-s to MeV/c^2 .

If $\mathbf{m} = \mathbf{h}(\mathbf{xSn})$ is correct, (and the factorings of hundreds of hadrons says it is) then a frequency of $(1.602176634 \times 10^{21} \text{ Hz})$ is associated with each unit of hypervolume of a hadron, no matter the dimension. In the example with \mathbf{Ds} (See next page), \mathbf{Ds} 's hypervolume is $10.000 \mathbf{S9}$, which equals $1967.053/\mathbf{h} = 296.8657$ hypervolume units. Multiplying 296.8657 by $(1.602176634 \times 10^{21} \text{ Hz/vol})$ - the frequency per unit hypervolume constant - will give you a frequency of $4.75631288 \times 10^{23} \text{ Hz}$ as the frequency associated with the entire particle, which is correct. Putting that frequency in Planck's energy-frequency law ($\mathbf{E}=\mathbf{hf}$) will give you the particle's mass in Joules. So in terms of particle *hypervolume*, Planck's energy-frequency law can be rewritten as:

$$\begin{aligned} \mathbf{E}_J &= \mathbf{h}_{\text{J-s}}(\text{volume}) (1.602176634 \times 10^{21} \text{ Hz/vol}) && \text{(here } \mathbf{h} = 6.62607015 \times 10^{-34} \text{ J-s)} \\ \mathbf{E}_J &= \mathbf{h}_{\text{J-s}}(\mathbf{xSn}) (1.602176634 \times 10^{21} \text{ Hz/vol}) && \text{(here } \mathbf{h} = 6.62607015 \times 10^{-34} \text{ J-s)} \end{aligned}$$

Which says a frequency (and therefore energy) is associated with a volume. \mathbf{E} will be in Joules. To convert \mathbf{E} to units of MeV/c^2 divide both sides by $1.602176634 \times 10^{-13} \text{ Joules}/\text{MeV}/c^2$ (the Joules to MeV/c^2 conversion factor). The result is \mathbf{E} in units of MeV/c^2 on the left and a factor of 10^{34} times $\mathbf{h}(\mathbf{xSn})$ on the right. When 10^{34} is multiplied by Planck's constant, $(6.62607015 \times 10^{-34})$, you are left with just Planck's constant's coefficient $(6.62607015 \text{ MeV}/c^2)$ for \mathbf{h} , which now has units of MeV/c^2 . The result is:

$$\mathbf{m}_{\text{MeV}} = \mathbf{h}_{\text{MeV}}(\mathbf{xSn}) \quad \text{(So, here } \mathbf{h} = 6.62607015 \text{ MeV}/c^2, \text{ not } 6.62607015 \times 10^{-34} \text{ J-s.)}$$

Where \mathbf{m} is in units of MeV/c^2 , $\mathbf{h} = 6.62607015 \text{ MeV}/c^2$, and \mathbf{Sn} is the hypervolume calculated from the surface volume formula for an n-sphere using a radius of one (a unit radius). \mathbf{Snh} values are given in an appendix for all \mathbf{n} from dimensions 2 to 21. That formula seems to work on any dimension of hadron, *which implies that the mass density of the hypervolume of hadrons remains the same over all dimensions*. What is the density of the hypervolume of any hadron? It is $6.62607015 \text{ MeV}/c^2$ per unit hypervolume. That's what the formula says if it is rearranged.

$$\mathbf{h}_{\text{MeV}} = \mathbf{m}_{\text{MeV}} / (\mathbf{xSn})$$

So, if $\mathbf{m}=\mathbf{h}(\mathbf{xSn})$ is valid, it means that if a correct factoring can be found for a hadron then, a precise mass, hypervolume, hyperdensity, and frequency can be assigned to it.

More Proof That Hadrons Are Made of Higher Dimensional Matter

More examples of higher dimensional hadrons follows, from dimension 4 to 18. Also, there are four appendices of useful information.
